Nature

A WEEKLY

ILLUSTRATED JOURNAL OF SCIENCE

VOLUME LXXXII

NOVEMBER, 1909, to FEBRUARY, 1910

"*To the solid ground*
Of Nature trusts the mind which builds for aye."—WORDSWORTH

SMITHSONIAN
LIBRARY

London
MACMILLAN AND CO., LIMITED
NEW YORK: THE MACMILLAN COMPANY

Richard Clay and Sons, Limited,
bread street hill, e.c., and
bungay, suffolk.

INDEX.

ABBE, Die Glasindustrie in Jena, ein Werk von Schott und, 391
Abbott (W. J. Lewis), So-called "Pygmy" Flint Weapons, 291
Abel (Prof. O.), Restoration of the Skeleton of *Eurhinodelphis cocheteuxi*, 16
Abel (Dr. Williamina), Development of the Autonomic Nervous Mechanism in the Alimentary Canal of the Bird, 479
Abney (Sir W. de W.), Change in the Hue of Spectrum Colours by Dilution with White Light, 175; Extinction of Colour by Reduction of Luminosity, 418
"Absorbing Matter" in Space, the Question of, Prof. Barnard, 500
Absorption of Light in Space, Prof. Kapteyn, 166
Absorption Spectra, an Atlas of, Dr. C. E. K. Mees, 336
Absorption-bands in Colourless Liquids, Prof. W. N. Hartley, F.R.S., 157
Ackermann (A. S. E.), the Flow of Sand, 487
Acquired Characters, the Inheritance of, A. Bacot, 98; Prof. Arthur Dendy, F.R.S., 98; Prof. H. Charlton Bastian, F.R.S., 157
Adam (J. C.), Long Nesting-period of the More Typical Members of the Crow-tribe, 198
Adami (Prof. J. George, F.R.S.), the Principles of Pathology, 94
Adams (L. E.), Breeding Habits of the Common Mole, 89
Adams (Prof.), Sun-spot Spectra, 19; the "Flash" Spectrum without an Eclipse, 47
Adsorption, Alfred Tingle, 279
Aëronautics: Conditions of Award of 1000*l.* Prize for British-built Aëronautical Engine, 201; International Kite and Balloon Ascents, Prof. Hergesell, 226; New Apparatus for Testing Aëroplane Models, C. E. Larard and R. O. Boswall, 227; Death of William Abner Eddy, 315; Current Autographic Records of Wind Velocity from Anemograph Stations, 404; Statistics of Aëronautical Patents, Dr. W. A. Dyes, 466
Africa: South African Association for the Advancement of Science, 38; Marine Investigations in South Africa, 145; Report of a Magnetic Survey of South Africa, Prof. J. C. Beattie, 285; Third Annual Report, of the Committee of Control of the South African Locust Bureau, 314; Recent Work of Geological Surveys, II. South Africa and Australasia, 443; an Introduction to the Geology of Cape Colony, Dr. A. W. Rogers and A. L. Du Toit, 454; In the Grip of the Nyika, Further Adventures in British East Africa, Lieut.-Col. J. H. Patterson, D.S.O., Sir H. H. Johnston, G.C.M.G., K.C.B., 283
Agar (Dr. W. E.), Nesting Habits of the Tree-frog, *Phyllomedusa sauvagii*, 269
Aged Tadpoles, John Don, 458; Oswald H. Latter, 489
Agriculture: Reports of the Connecticut Agricultural Station for 1907–8, 17; Recent Agricultural Publications from the West Indies, 23; Agriculture in Peru, 44; Culture of Maize, Mr. Burtt-Davy, 44; Winter Fumigation for the White Fly infesting Citrus Trees, 76; Cattle of Southern India, Lieut.-Col. W. D. Gunn, 96; Journal of the Tokyo College of Agriculture, 105; Improvement in Paddy Cultivation, 105; Notes on Cacao, 105; Report of the Botanic Station Agricultural School and Experimental Plots, St. Lucia, 138; the Bird Problem in Relation to Agriculture, 138; Manurial Experiments on the Sugar-cane, 163; Irish Potato Blight in Australia, 163; Black Scab of the Potato, M. Hegyi, 480; Investigations on Various Nitrogenous Manures, Messrs. Voorhees and Lipman, 163; Irrigation and Methods of Dry-farming in South Africa, 163; Cows, Cowhouses, and Milk, G. Mayall, 188; Annual Report on the Distribution of Grants for Agricultural Education and Research in the Year 1907–8, 193; Effects produced by Partial Sterilisation of Soils, Drs. E. J. Russell and H. B. Hutchinson, 199; Problem of Nitrogen Assimilation by Plants, Drs. H. B. Hutchinson and N. H. J. Miller, 199; Nitrogen-fixing Bacteria and Non-leguminous Plants, Prof. W. B. Bottomley, 218; A. D. Hall, F.R.S., 218; the Chinch-bug (*Blissus leucopterus*) and its Ravages, 226; Production and Utilisation of Molasses, 264; Relations between Birds and Insects, F. E. L. Beal, 290; Economic Value of Predaceous Birds and Mammals, A. K. Fisher, 291; Poisons used for Destroying Noxious Mammals, Dr. E. Lantz, 291; Annual Report from the Experimental Station, Tortola Virgin Islands, 317; Lucerne Growing in South Africa and *Tylenchus dipsaci* (*devastatrix*), 317; the Cultivation of Shellac, Mr. Maxwell-Lefroy, 317; Banana Spirit, 317; Spirit from Raisins, Prof. Perkins, 318; Électricité agricole, A. Petit, 334; Cotton Growing in British East Africa, 345; Manurial Trials on Cotton Soils, Dr. Whitney, 346; Cotton and Arrowroot in St. Vincent, 438; Cyclopedia of American Agriculture, Dr. E. J. Russell, 361; Function of Phosphates in the Nutrition of Animals, 375; Phosphate Contents of Soils, 375; New Varieties of Ground Nuts introduced into West Indies, 375; Uredineæ Parasitic on the Japanese Gramineæ, S. Ito, 375; West Indian Bulletin, 376; Artificial Manures, their Chemical Selection and Scientific Application to Agriculture, M. Georges Ville, Dr. E. J. Russell, 421; Prevention of Damage by Frosts in Orchards, Prof. A. G. McAdie, 438; Report of the Botanic and Experiment Stations in Montserrat, 466; the Fertilising Influence of Sunlight, A. Howard and G. L. C. Howard, 456; Influence of Culture on the Amount of Alkaloids in some Solanaceæ, J. Chevalier, 480; Text-book of Egyptian Agriculture, 482; Agriculture in the Tropics, Dr. J. C. Willis, 492
Agulhon (H.), Use of Boron as a Catalytic Manure, 450
Air and Health, R. C. Macfie, 397
Aitken (Dr. John, F.R.S.), Atmospheric Cloudy Condensation, 8; the Temperature of the Upper Part of Clouds, 67
Albe (Fournier D'), Recent Advances in Electrical Theory, 376
Albrecht (Dr.), the New Comet 1910*a*, 441
Alcock (Dr. N. H.), a Text-book of Experimental Physiology for Students of Medicine, 97
Algebra: Theorie der algebraischen Zahlen, Dr. Kurt Hensel, 95; Exercise Papers in Elementary Algebra, Rev. E. M. Radford, 275
Algometer, Temporal, Arthur Macdonald, 316

Alkali-syenites in Ayrshire, G. W. Tyrrell, 188

Allen (Dr. F. J.), the New Comet 1910*a*, 441

Alloys: Leçons sur les Alliages métalliques, Prof. J. Cavalier, 62

Alpes, Région des, Service d'Études des grandes Forces hydrauliques, 93

Alternating Current Commutator Motor and the Leakage of Induction Motors, the, Dr. Rudolf Goldschmidt, Prof. Gisbert Kapp, 244

Amaftounsky (M.), an Interesting Sun-spot, 259

Ameisenleben, Bilder aus dem, H. Viehmeyer, 34

America: Cave Vertebrates of America, Prof. Carl H. Eigenmann, Prof. Arthur Dendy, F.R.S., 40; Tuberculosis among Certain Indian Tribes of the United States, Dr. Ales Hrdlička, 130; Epidemic Disease among the North American Indians, Dr. H. U. Williams, 266; American Federation of Teachers of the Mathematical and the Natural Sciences, G. F. Daniell, 284; the Boston Meeting of the American Association, 342; Cyclopedia of American Agriculture, Dr. E. J. Russell, 361; Surface Water Supply of the United States, 1907–8, South Atlantic Coast and Eastern Gulf of Mexico, M. R. Hall and R. H. Bolster, 379; Underground Water Resources of Connecticut, Herbert E. Gregory, Occurrence of Water in Crystalline Rocks, E. E. Ellis, 379

Ammonites, Yorkshire Type, 455

Anæsthesia, Spinal, 99

Anatomy: the Brain of Prof. D. J. Mendeléeff, Profs. W. von Bechterew and R. Weinberg, 16; the Asymmetry of the Human Body, Prof. E. Gaupp, 16; Individual Variation in the Degree of Development of the Muscular Impressions, Crests, or Tubercles of the Appendicular Skeleton of the Human Subject, Dr. Campbell Geddes, 43; Early Stages in the Development of the Aortic Arches in the Cat, C. B. Coulter, 289; Some Problems Relating to the Evolution of the Brain, Prof. G. Elliot Smith, F.R.S., at Royal College of Surgeons, 349; Vergleichende Anatomie der Wirbeltiere, Dr. Robert Wiedersheim, 362

Ancient Ideas of the Physical World, Leon Jaloustre, 320

André (Ch.), the Johannesburg Comet, 448

Andrew (A. R.), the Geology of Nyasaland, 147; Detection of Minute Traces of Gold in Country Rock, 509

Andrews (E. C.), "The Danger of the Comet," 162

Angot (Alfred), Earthquake of October 20–21, 1909, 30; Earthquake of November 10, 1909, 120; Earthquake of January 22, 1910, 449

Animal Physiology, the Elements of, Prof. W. A. Osborne, 97

Animal Psychology, the Method of Pawlow in, R. M. Yerkes and S. Morgulis, 203

Animals of Australia, the, A. H. S. Lucas and W. H. Dudley le Souëf, 453

Animals and their Story, the, W. P. Westell, 423

Animals and their Ways, E. Evans, Dr. C. Gordon Hewitt, 395

Annandale (Dr. N.), *Alaptus magnanimus*, 496

Anniversary Meeting of the Royal Society, 131; Presidential Address at, Sir Archibald Geikie, 132

Annuaire Astronomique, Belgium, the, 349

Annuaire Astronomique et Météorologique, 1910, 293

Annuaire of the Bureau des Longitudes, the, 107

Annuaire for 1910 of the Madrid Observatory, 378

Ant Communities and how they are Governed, Dr. H. C. McCook, 276

Antarctica: Die Schwerkraftsbestimmungen der Deutschen Südpolar-Expedition, E. von Drygalski and L. Haasemann, 69; Deutsche Südpolar-Expedition, 1901–1903, 336; Paris Geographical Society Gold Medal awarded to Sir Ernest Shackleton, 73; Livingstone Gold Medal of the Royal Scottish Geographical Society presented to Sir Ernest Shackleton, 102; the Heart of the Antarctic, being the Story of the British Antarctic Expedition, 1907–9, Sir E. H. Shackleton, C.V.O., Prof. J. W. Gregory, F.R.S., 280; British Antarctic Expeditions, 315; the Mean Height of the Antarctic Continent, Prof. W. Meinardus, 343; Sir Ernest Shackleton and Antarctic Exploration, 344; Russian Geographical Society's Gold Medal awarded to Sir Ernest Shackleton, 403; Proposed United States South Polar Expedition, Commander Robert E. Peary, 435; Life Under Antarctic Conditions, James Murray, 448; the French Antarctic Expedition, 460

Anthropology: Royal Anthropological Institute, 147, 177, 238, 478; Origin of Sexual Antipathy among near Relations, W. G. Aston, 163; Pit-dwellings at Holderness, Canon Greenwell and the Rev. R. A. Gatty, 177; Results of a recent Ethnographical Expedition to the Congo Free State, E. Torday, 238; the Human Race: its Past, Present, and Probable Future, J. Samuelson, 277; Origin of the Upright Posture in Man, Drs. P. and E. von Hass, 289; System of Tattooing in Vogue in Persia, Major P. M. Sykes, 291; So-called "Pygmy" Flint Weapons, W. J. Lewis Abbott, 291; Aborigines of Tasmania, Part ii., the Skeleton, Sir William Turner, 358; Shell Mounds of the San Francisco Bay Region, N. C. Nelson, 438; Remarkable Wooden Statue from the Kasai District in West Africa, T. A. Joyce, 464; the Madang Tribe, Dr. C. Howe, 464; the Discovery of a Skeleton of Palæolithic Man, Dr. Capitan and M. Peyrony, 492

Antiseptics: the Collected Papers of Joseph, Baron Lister, 451

Antoniadi (M.), Seasonal Change on Mars, 107; Observations of the Planet Mars made at Meudon Observatory, 119; Observations of Mars, 140; Subjective Phenomena on Mars, 227

Antoonovich (Chr.), Uranium Ore as a Remedy, 189

Aquarium, the Freshwater, and its Inhabitants, Otto Eggeling and Frederick Ehrenberg, 34

Aquarium, the Marine, Madras, 411

η Aquilæ, Photographic Observations of, A. Kohlschütter, 500

Arachnida, Introduction to, and King-Crabs, the Cambridge Natural History, A. E. Shipley, 211

Aral, the Sea of, Prof. Woeikow, 13

Arber (E. A. N.), Description of the Fossil Flora, Nyasaland, 147

Archæology: the Gallop of the Horse and the Dog, Sir E. Ray Lankester, K.C.B., F.R.S., 7; Discovery of Two Interesting Bronze Statuettes at Malton, Yorkshire, T. Sheppard, 18; Stone Implements from the Tongyueh District, J. C. Brown, 30; Beiträge zur Naturdenkmalpflege, Prof. H. Conwentz, A. E. Crawley, 40; Clay Figure Unearthed in a Stone-age Dwelling at Ottitz, 42; Norwegian Antiquities, Haakon Schetelig, 43; Ancient Bronzes in Colombo Museum, P. Arunachalam and D. Wickremasimghe, 164; Return of Central Asia Expedition under MM. Paul Pelliot and Nonette, 197; the Atrium Vestæ at Rome, Miss E. B. van Deman, 200; Excavations at Maumbury Rings, Discovery of the *Cavea*, St. George Gray, 406; a Note on the Gilded Metal-work of Chiriqui, Central America, Oswald H. Evans, 457; Dolmens of Peculiar Types in France and Elsewhere, A. L. Lewis, 478; Existence of a Palæolithic Bed beneath the Glacial Boulder-clay in South-west Suffolk, Dr. J. S. Holden, 478; Prehistoric Remains near Cheltenham, Dr. A. M. McAldowie, 496

Archenhold (Herr), Halley's Comet 1909*c*, 378

Architectural Copyright, Question of, G. T. Brown, 106

Architecture, Naval, H.M.S. *Collingwood*, 467

Arctica: National Geographic Society awards Gold Medal to Commander Peary, 42; Dr. Cook's Polar Journey, 225; Royal Geographical Society award a Gold Medal to Commander Peary, 373

Aries (Lieut.-Colonel E.), l' lectricité considérée comme Forme de l'Énergie, 484

Aristotelian Society, Proceedings of the, Prof. A. E. Taylor, 155

Arithmetic, Practical, for Schools, W. G. Borchardt, 425

Armitage (Eleonora), the New Comet 1910*a*, 441

Armstrong (Prof. H. E., F.R.S.), Low-temperature Research at the Royal Institution of Great Britain, London, 1900–7, 131; the Meaning of "Ionisation," 458, 487

Arrhenius (Svante), zur Feier des 25-jährigen Bestandes seiner Theorie der elektrolytischen Dissociation gewidmet von seiner Freunden und Schülern, Prof. James Walker, F.R.S., 401

Arunachalam (P.), Ancient Bronzes in Colombo Museum, 164

Arve in der Schweiz, Die, Dr. M. Rikli, 399

Asher (Prof.), der Physiologische Stoffaustausch zwischen Blut und Geweben, 199–200

Asiatic Society of Bengal, 30, 240, 390

Aston (W. G.), Origin of Sexual Antipathy among Near Relations, 163

Astronomy: the Systematic Motions of the Stars, Prof. F. W. Dyson, F.R.S., 11; Changes on Mars, M. Jarry-Desloges, 19; Dimensions and Function of the Martian Canals, Dr. H. C. Pocklington, 58; the Functions of the Martian Canals, H. F. Hunt, 69; Recent Observations of Mars, M. Jonckheere, 77; M. Jarry-Desloges, 77; Seasonal Change on Mars, Prof. Lowell, 107; M. Antoniadi, 107; M. Quénisset, 107; J. Comas Sola, 107; Ocular and Photographic Observations of the Planet Mars, M. Idrac, 119; Observations of the Planet Mars made at the Observatory, Meudon, E. M. Antoniadi, 119; Photography of the Planet Mars, A. de la Baume Pluvinel and F. Baldet, 119; Observations of Mars, M. Jonckheere, 140; M. Antoniadi, 140; M. Idrac, 140; MM. de la Baume Pluvinel and F. Baldet, 140; M. Kostinsky, 140; the New Canals of Mars, Prof. Percival Lowell, 189; Mars, Rev. T. E. R. Phillips, 202; Prof. Lowell, 408; Résumé of Observations of Mars made at the Fabra Observatory, Barcelona, during the Opposition of 1909, J. Comas Sola, 209; Subjective Phenomena on Mars, M. Antoniadi, 227; M. Jonckheere, 227; Oppositions of Mars, Enzo Mora, 320; Markings on Mars as seen with Small and Large Telescopes, Dr. Percival Lowell, 397; Gradual Retreat of the Southern Polar Cap of Mars, R. Jarry-Desloges, 299; Markings on Mars, Prof. Lowell, 440; Halley's Comet, 1909*c*, 19, 165, 201; Prof. Wolf, 19; Knox Shaw, 19, 319; M. Javelle, 29; Prof. Barnard, 46, 319; Mr. Cowell, 47; Mr. Crommelin, 47, 140, 292, 320, 378, 499; Mr. Hollis, 140; Rev. T. E. R. Phillips, 140, 348; Dr. Graff, 202; H. Thiele, 202; Prof. Nijland, 227; Herr v. Buttlar, 227; MM. Deslandres and Bernard, 259; Prof. A. A. Iwanow, 259; Drs. Nijland and J. v. d. Bilt, 292; Mr. Keeling, 319; Pio Emanuelli, 319; Messrs. Frost and Parkhurst, 348; Earl of Crawford, 349; Prof. Searle, 378; Herr Archenhold, 378; Observations of Halley's Comet, M. Giacobini, 89; P. M. Ryves, 429; Suggested Observations of Halley's Comet, 260; Elements of Halley's Comet, P. H. Cowell, F.R.S., and A. C. D. Crommelin, 77; New Elements for Halley's Comet, C. J. Merfield, 440; the Spectrum of Halley's Comet, W. H. Wright, 107; H. Deslandres and A. Bernard, 230.; On Halley's Comet as seen from the Earth, P. H. Cowell, F.R.S., 400; Transit of Halley's Comet, Rev. C. S. Taylor, 458; Sun-spot Spectra, Prof. Adams, 19; an Interesting Sun-spot, M. Amaftounsky, 259; Radial Movements in Sun-spots, J. Evershed, 358; the Epoch of the Last Sun-spot Maximum, Dr. Wolfer, 378; Designations of Newly Discovered Variable Stars, 19; the Motions of Some Stars in Messier 92 (Hercules), Prof Barnard, 19; Our Astronomical Column, 19, 46, 77, 107, 140, 165, 201, 227, 259, 292, 319, 348, 378, 408, 440, 468, 499, Solar Vortices and Magnetic Fields, Prof. George E. Hale, For.Mem.R.S., at Royal Institution, 20, 50; Observations of the Sun at the Observatory of Lyons, J. Guillaume, 29; the Temperature of β Perseus (Algol), Charles Nordmann, 29; November Meteors, John R. Henry, 38; New Astronomical Observatory and Meteorological Station on Hampstead Heath, 42; Astronomical Occurrences in November, 46; in December, 140; in January, 292; in February, 408; Re-discovery of Winnecke's Comet (1909*d*), Prof. Hillebrand, 46; Winnecke's Comet, Dr. Perrine, 378; Ephemerides for Winnecke's Comet, 1909*d*, Prof. Hillebrand, 202; Saturn, 47; Mercury, M. Jarry-Desloges, 47; Period of Rotation of, M. Jarry-Desloges, 178; the "Flash" Spectrum without an Eclipse, Messrs. Hale and Adams, 47; Search-ephemeris for Giacobini's Comet, 1896 V, 47; a Brilliant Meteor, 77; Perrine's Comet, 1909*b*, Dr. Kobold, 78; Prof. Wolf, 140; Ephemerides for, Dr. Ebell, 202; the Liverpool Astronomical Society, 78; the Parallax of the Double Star Σ 2398, Dr. Bohlin, 78; Prof. Schlesinger, 78; Means of Removing Astronomical Clocks from the Influence of the Variations of Atmospheric Pressure, G. Bigourdan, 89; Atmospheric Refraction, Rev. W. Hall, 107; the Perseid Meteors in 1909, Mr. Oliver, 107; a Daylight Meteor, Dr. Palisa, 107; Spectroscopic Binaries, Dr. S. A. Mitchell, 107; the "Annuaire" of the Bureau des Longitudes, 107; Relative Periods of Revolution of Planets and Satellites, C. E. Stromeyer, 119; Movements of the Red Spot Hollow on Jupiter, Scriven Bolton, 128; Observations of Jupiter, H. E. Lau and C. Luplau-Jannsen, 202; Dr. H. H. Kritzinger, 202; Simultaneous Disappearances of Jupiter's Satellites 1800–1999, Enzo Mora, 320; the Design of Spectrographs, J. Plaskett, 140; the Astronomical Society of Wales, 140; British Astronomical Association, 140; "The Danger of the Comet," E. C. Andrews, Prof. C. A. Young, 162; Discovery of a New Comet 1909*e*, Prof. Daniel, 165; Daniel's Comet, 1909*e*, Prof. Daniel, 201; Dr. Ebell, 201, 227; Elements and Ephemeris for Daniel's Comet, 1909*e*, Dr. Ebell, 292; Observations of, M. Borrelly, 299; P. Chofardet, 299; a Possible Identification of Comet 1909*e*, P. H. Cowell, F.R.S., 427; Elliptic Elements and an Ephemeris for Daniel's Comet, 1909*e*, Dr. Ebell, 468; Ephemeris for Daniel's Comet, 1909*e*, 500; Absorption of Light in Space, Prof. Kapteyn, 166; Copernicus Anticipated, Pierre Duhem, 166; Star Almanac and Calendar for 1910, 166; How to Study the Stars, L. Rudaux, 187; How to Identify the Stars, Dr. Willis I. Milham, 187; Collected Works of Sir William Herschel, Dr. T. J. J. See, 189; a Solar Physics Observatory for Australia, 202; the Hamburg Observatory, 202; Temperature Classification of Stars, Drs. Wilsing and Scheiner, 228; Dr. Nordmann, 228; a New Variable Star, or a Nova, Mme. Ceraski, 228; the "Companion to the Observatory," 228; Observations of Comets made at the Marseilles Observatory, M. Coggia, 239; History of Astronomy, Prof. G. Forbes, F.R.S., 245; Death of M. Bouquet de la Grye, 256; Obituary Notice of, 286; Periods in the Variation of Latitude, Jan Krassowski, 259; the Planet Venus, Prof. Lowell, 260; Sextant Errors, Thos. Y. Baker, 276; Solar Activity and Magnetic Storms, Dr. W. J. S. Lockyer, 293; Father Cortie, 293; Michie Smith, 293; Star Swarms, Prof. Turner, 293; Herr Kostinsky, 293; a Large Nebula in Cetus, Prof. Wolf, 293; Annuaire Astronomique et Météorologique, 1910, 293; the Tercentenary of the Telescope, Dr. J. L. E. Dreyer, 190; J. A. Hardcastle, 308; a Brilliant Fireball, Mr. Denning, 320; Ancient Ideas of the Physical World, Leon Jaloustre, 320; Minor Planets, Dr. Neugebauer, 320; the Total Solar Eclipse of May 8, 320; Comets due to Return this Year, Mr. Lynn, 320; Other Periodic Comets due to Return this Year, Dr. Hopfer, 378; Les Progrès récents de l'Astronomie (1908), Prof. Paul Stroobant, 336; Royal Astronomical Society's Gold Medal Awarded, 343; Discovery of a New Comet, 348; the New Comet (1910*a*), 372, 409; W. E. Rolston, 372; Father Cortie, 440; William McKeon, 440; Father Sidgreaves, 441; Rev. J. Rowland, 441; Theodore Kensington, 441; Eleonora Armitage, 441; Dr. F. J. Allen, 441; Prof. R. A. Gregory, 441; M. Giacobini, 441; M. Chofardet, 441; Mdlle. de Robeck, 441; Mr. Keeling, 441; Dr. Albrecht, 441; MM. Deslandres, Bernard, and d'Azambuja, 442; Dr. Schiller, 442; Gustave Gillman, 468; Lucien Rudaux, 468; Mr. Hinks, 468; MM. Luizet and Guillaume, 468; M. Borrelly, 468; MM. Javelle, Charlois, and Schaumasse, 468, 479; Mr. Innes, 499; Dr. Kobold, 499; E. Esclangon, 499; M. Borrelly, 499; the Johannesburg Comet, Ch. André, 448; Observations of Comet 1910*a* at the Observatory of Meudon, H. Deslandres, A. Bernard, and L. d'Azambuja, 449; Transformations of the Innes Comet (1910*a*), Ernest Esclangon, 509; Intermittent Glow of the Tail of the New Comet, J. H. Elgie, 399; the Spectra of Comets' Tails, Prof. A. Fowler, 349; Two Curiously Similar Spectroscopic Binaries, 349; the "Annuaire astronomique," Belgium, 349; Royal Astronomical Society, 358; Astronomische Abhandlungen der Hamburg Sternwarte in Bergedorf, 365; Annuaire for 1910 of the Madrid Observatory, 378; Death and Obituary Notice of Sir Charles Todd, K.C.M.G., F.R.S., 403; Caroline Herschel and her Comet Seeker, 408; Studies of Solar and Stellar Spectra, Count A. de Gramont, 440; Elements and Ephemeris for Tempel's Comet (1873 II.), M. Maubant, 440; Aspects of Astronomy, Sir David Gill at Royal Astronomical Society, 463; the Magnetic Storm of September, 1909, and Solar Phenomena, M. Deslandres, 468; the Intrinsic Light of the Sky, Ch. Fabry, 468; Publications of the Lund Observatory, Sweden, 468; the Spectrum of the Zodiacal Light, W. E. Rolston, 470; Discovery of a New Comet, 1910*b*, M. Pidoux, 499; the

Question of "Absorbing Matter" in Space, Prof. Barnard, 500; Photographic Observations of η Aquilæ, A. Kohlschütter, 500; Brilliant Meteor of February 17, W. F. Denning, 500
Astrophysics: the Absence of a Lunar Atmosphere, Charles W. Raffety, 38; l'Assorbimento selettivo della Radiazione solare nell' Atmosfera terrestre e la sua variazione coll' altezza, Dr. A. Bemporad, Dr. C. Chree, F.R.S., 78; Nature of the Diffraction Figures due to the Heliometer, P. F. Everitt, 176; Sun's Motion with Respect to the Æther, Dr. C. V. Burton, 177; New Approximation in the Study of the Effective Temperatures of the Stars, Ch. Nordmann, 209
Athanasiadis (G.), Influence of Temperature on the Phenomena of Polarisation in the Electrolytic Valve, 29

Photo-micrography, Elementary, Walter Bagshaw, J. E. Barnard, 97

Photo-telegraphy: Recent Work in the Telegraphic Transmission of Pictures, T. Thorne-Baker, 309

Phthisis and Insanity, on the Inheritance of the Diathesis of, Dr. Charles Goring, 204

Physics: the Refractivity of Radium Emanation, Prof. Alfred W. Porter and Clive Cuthbertson, 7; the Atomic Weight of the Radium Emanation, Frederick Soddy, 188; the Small Motion at the Nodes of a Vibrating String, C. V. Raman, 9; High-pressure Spark Gap in an Inert Gas, Rev. F. J. Jervis-Smith, F.R.S., 9; Modified Form of Favre and Silbermann Calorimeter, Dr. H. Schottky, 18; Converting a Celluloid Copy of a Diffraction Grating into a Reflecting Grating, Drs. E. Gehrcke and G. Leithauser, 18; Emission of Gases by Heated Metals, G. Belloc, 29; an Introduction to Physical Science, Dr. F. H. Getman, 35; an Elementary Course in Practical Science, C. Foxcroft and S. J. Bunting, 35; a New Barograph, T. Shida, 45; Cooling of the Air in a Liquefying Apparatus, W. P. Bradley and C. F. Hale, 45; Cadmium Amalgams and the Weston Normal Cell, F. E. Smith, 58; Physical Society, 58, 146, 177, 476, 508; Experiments at High Temperatures and Pressures, Richard Threlfall, F.R.S., at Royal Institution, 82; a Compound Pendulum of very Simple Construction giving immediately the Length of the Synchronous Pendulum, H. Pellat, 89; the Frigorific Recuperation of Volatile Liquids lost in various Industries, Georges Claude, 90; Harmonic Vibrations and Vibration Figures, J. Goold, C. E. Benham, R. Kerr, and Prof. L. R. Wilberforce, Prof. C. V. Boys, F.R.S., 96; Discontinuities in Light-emission, N. R. Campbell, 118; Theory of the Motion of a Charged Particle through a Gas, Sir J. J. Thomson, 118; Vapour Pressure of an Electrified Liquid, M. Gouy, 119; "Savants du Jour," Henri Poincaré, 139; Desiccation of Air before Liquefaction, Georges Claude, 149; Conditions Necessary for Platinum to Remain in a State of Incandescence in a Bunsen Burner, Jean Meunier, 149; Osmotic Pressure in Plants and on a Thermo-electric Method of Determining Freezing Points, Prof. Henry H. Dixon and W. R. G. Atkins, 148; the Maintenance of Forced Oscillations of a New Type, C. V. Raman, 156, 428; the Terminal Velocity of Fall of Small Spheres in Air, Prof. John Zeleny and L. W. McKeehan, 158; Edith A. Stoney, 279; Velocity of Steady Fall of Spherical Particles through a Fluid Medium, E. Cunningham, 419; the Motional Effects of the Maxwell Æther-stress, E. Cunningham, 176; Effective Resistance and Inductance of a Helical Coil, Dr. J. W. Nicholson, 177; Ductile Materials under Combined Stress, W. A. Scoble, 177; Studies on very Short Electro-magnetic Waves, H. Merczyng, 178; Results of Re-measurement of the Magnetic and Electrical Properties of Steel Rods made Glass-hard and then Tested by Prof. Barus in 1885, Laura L. Brant, 200; Advantages of Using Calcium Carbide as a Drying Material in Electrostatic Instruments, Dr. T. Wulf, 200; the New Physics, Sound, Joseph Battell, 216; Experimental Foundations of the Atomic Theory, Werner Mecklenburg, 227; the Physical Society's Exhibition, 234; the Wimperis Accelerometer, 234; an Accelerometer, A. P. Trotter, 234; Gas-leakage Indicator, 234; Daylight Illumination Photometer, A. P. Trotter, 234; Application of Abraham's Rheograph to Throw on the Screen a Hysteresis Loop, 234; Dr. C. V. Drysdale's Slip Meter, 234; Dr. C. V. Drysdale's Potentiometer for Alternating Currents, 234; Radium Collector for Atmospheric Electricity, F. Harrison Glew, 234; Apparatus for Transmitting Photographs Electrically, T. Thorne-Baker, 234; Direction of Motion of the Electrons Ejected by the α Particle, R. D. Kleeman, 237; Conduction of Heat through Rarefied Gases, F. Soddy and A. J. Berry, 237; Waves in a Dispersive Medium resulting from a Limited Initial Disturbance, G. Green, 239; Arrangement for the Determination of very Small Differences of Pressure, A. Lafay, 239; Death of Dr. Shelford Bidwell, F.R.S., 224; Obituary Notice of, 252; Improved Störmer Viscosimeter, 258; Motion of an Electrified Sphere, Prof. A. W. Conway, 270; the Ether of Space, Sir Oliver Lodge, F.R.S., 271; the Heat Developed during the Absorption of Electricity by Metals, Profs. O. W. Richardson and H. L. Cooke, 278; on Fluorescence Absorption, J. Butler Burke, 279; Death and Obituary Notice of Prof. J. S. H. Pellat, 287; Re-determination of the Constant of Stefan's Law, MM. Bauer and Moulin, 178, 291; the Constant in Stefan's Law and the Radiation of Platinum, Edmond Bauer and Marcel Moulin, 389; New Modification of the Cloud Method of Measuring the Elementary Electrical Charge, Prof. R. A. Millikan, 291; Influence of a Magnetic Field on the Damping of Light Vibrations, Jean Becquerel, 299; Preparation of Thin Films by Volatilisation in a Vacuum, L. Houllevigue, 299; Application of the Ultra-microscope to the Study of the Phenomena of Electrolysis, Dr. J. J. Kossonogow, 318; Degree of Completeness of the Circular Polarisation of magnetically divided Lines, Prof. Zeeman, 319; Lord Kelvin's Early Home, Mrs. Elizabeth King, 331; Electrons, Prof. W. Wien, 346; Calculation of Sizes of the Particles Shot off from a Silver Kathode in a Vacuum Tube, L. Houllevigue, 346; Frequency Meter Constructed from the Designs of Commandant Ferrié and on a Small Precision Balance Constructed by M. Collot, J. Carpentier, 359; Upper-air Temperatures Registered Outside and Inside Balloons, W. A. Harwood, 366; Death of Prof. F. Kohlrausch, 373; Obituary Notice of, 402; Measurements of the Brownian Movements in Emulsions of Gamboge and of Mastic, Jean Perrin, 376; Contributions to the Theory of Screws, Sir Robert S. Ball, 389; Electric Cohesion of Neon, E. Bouty, 389; Initial Accelerated Motion of Electrified Systems of Finite Extent and the Reaction produced by the Resulting Radiation, G. W. Walker, 418; Svante Arrhenius zur Feier des 25-jährigen Bestandes seiner Theorie der elektrolytischen Dissociation gewidmet von seiner Freunden und Schülern, Prof. James Walker, F.R.S., 401; Gas-washing Bottles with a very Slight Resistance to the Passage of Gas, Dr. A. C. Cumming, 420; the Vapour Pressures, Specific Volumes, Heats of Vaporisation and Critical Constants of Thirty Pure Substances, Prof. S. Young, 448; Laws of Evaporation, P. Vaillant, 449; Systematic Error in the Determination of the Mean Level of the Sea by the Medimaremeter, Ch. Lallemand, 449; the Meaning of "Ionisation," Prof. Henry E. Armstrong, F.R.S., 458, 487; Prof. James Walker, F.R.S., 458; Death of Prof. H. Dufour, 464; Work of the Physical Society, Dr. Chree, 464; Saturation, Specific Heats, &c., with van der Waals's and Clausius's Characteristics, R. E. Baynes, 476; Propagation of a Disturbance in a Fluid under Gravity, F. B. Pidduck, 476; Polarisation of Dielectrics in a Steady Field of Force, Prof. Thornton, 477; the Use of Mutual Inductometers, A. Campbell, 477; Variation of the Inertia of the Electron as a Function of the Velocity in the Kathode Rays and on the Principle of Relativity, C. E. Guye and S. Ratnovsky, 479; Emission of Electric Charges by the Alkaline Metals, Louis Dunoyer, 479; L'Électricité considérée comme Forme de l'Énergie, Lieut.-Colonel E. Aries, 484; Lehrbuch der Physik, E. Grimsehl, 484; Elements of Physics for Use in High Schools, H. Crew, 484; Light, Prof. R. C. Maclaurin, 484; the Flow of Sand, A. S. E. Ackermann, 487; Charles E. S. Phillips, 487; Secondary Cells in Tropical Climates, Prof. E. P.

Harrison, 489; Two Mercury Manometers for Small Pressures, Drs. Karl Scheel and Wilhelm Heuse, 498; Re-combination of Ions at Different Temperatures, D. P. Phillips, 507; Scattering of the *a* Particles by Matter, Dr. H. Geiger, 507; the Ionisation produced by an *a* Particle, Dr. H. Geiger, 508; Influence of Pressure on the Boiling Points of Metals, H. C. Greenwood, 508; Viscosities of the Gases of the Argon Group, A. O. Rankine, 508; Application of Resistance Thermometers to the Recording of Clinical Temperatures, Prof. H. L. Callendar, 508; Measurement of the Index of Refraction by Means of the Microscope, L. Décombe, 509

Laboratory Guide of Industrial Chemistry, Dr. Allen Rogers, 33
Zoologia, Angel Gallardo, 34
Einführung in die Biologie, Prof. Karl Kraepelin, 34
The Freshwater Aquarium and its Inhabitants, Otto Eggeling and Frederick Ehrenberg, 34
Bilder aus dem Ameisenleben, H. Viehmeyer, 34
Die Schwarotzer der Menschen und Tiere, Dr. O. von Linstow, 34
An Introduction to Physical Science, Dr. F. H. Getman, 35
An Elementary Course in Practical Science, C. Foxcroft, S. J. Bunting, 35
A Brief Course in the Calculus, W. Cain, 36
The Life of a Fossil Hunter, Charles H. Sternberg, 36
The Book of Nature Study, 37
Éléments de la Théorie des Probabilités, Émile Borel, 37
Cave Vertebrates of America, Prof. Carl H. Eigenmann, Prof. Arthur Dendy, F.R.S., 40

Beiträge zur Naturdenkmalpflege, Prof. H. Conwentz, A. E. Crawley, 40
Plaice-marking Experiments on the East Coast of Ireland in 1905 and 1906, G. P. Farran, 41
Bulletin Statistique des Pêches Maritimes des Pays du Nord de l'Europe, vol. iii., pour l'Année 1906, 54
Rapports et Procès-verbaux des Réunions, vol. xi., Juillet, 1907–Juillet, 1908, 54
Rapport sur les Travaux de la Commission dans le Période 1902–7, 54
Twenty-seventh Annual Report of the Fishery Board for Scotland for the Year 1908, 54
Zeitpunkt der Bestimmung des Geschlechts, Apogamie, Parthenogenesis, und Reduktionsteilung, E. Strasburger, Prof. J. B. Farmer, F.R.S., 62
Leçons sur les Alliages métalliques, Prof. J. Cavalier, 62
The Young Naturalist, W. P. Westell, 63
Nature, J. H. Crawford, 63
Victorian Hill and Dale, Dr. T. S. Hall, 63
Aufangsgründe der Maxwellschen Theorie, verknupft mit der Elektronentheorie, Franz Richards, 64
The Theory of Electrons, and its Applications to the Phenomena of Light and Radiant Heat, H. A. Lorentz, 64
Handbook of Marks on Pottery and Porcelain, W. Burton and R. L. Hobson, 65
The Races of Man and their Distribution, Dr. A. C. Haddon, F.R.S., 65
Der menschliche Organismus und seine Gesunderhaltung, Dr. A. Menzer, 66
Unsere Sinnesorgane und ihre Funktion, Dr. E. Mangold, 66
Die moderne Chirurgie für gebildete Laien, Dr. H. Tillmanns, 66
Die Geschlechtskrankheiten, ihr Wesen, ihre Verbreitung, Bekämpfung und Verhütung, Prof. Schumburg, 66
Plant Galls of Great Britain, Edward T. Connold, 66
The Rhodesian Miner's Handbook, F. P. Mennell, 66
Los Metodos de Integracion, Carlos Wargny, 66
Survey of India, the Pendulum Operations in India, 1903–7, Major G. P. Lenox Conyngham, 69
Deutsche Südpolar Expedition, 1901–3, die Schwerkrafts bestimmungen der Deutschen Südpolar Expedition, E. von Drygalski und L. Haasemann, 69
L'Assorbimento Selettivo della Radiazione Solare nell' Atmosfera terrestre e la sua variazione coll' altezza, Dr. A. Bemporad, Dr. C. Chree, F.R.S., 78
Charles Darwin and the Origin of Species, Addresses, &c., in America and England in the Year of the Two Anniversaries, Prof. E. B. Poulton, F.R.S., Prof. R. Meldola, F.R.S., 91
Service d'Etudes des grandes Forces hydrauliques (Région des Alpes), 93
The Principles of Pathology, Prof. J. George Adami, F.R.S., 94
Theorie der algebraischen Zahlen, Dr. Kurt Hensel, 95
Harmonic Vibrations and Vibration Figures, J. Goold, C. E. Benham, R. Kerr, Prof. L. R. Wilberforce, Prof. C. V. Boys, F.R.S., 96
Cattle of Southern India, Lieut.-Col. W. D. Gunn, 96
Flora of Cornwall, F. H. Davey, 97
The Elements of Animal Physiology, Prof. W. A. Osborne, 97
A Text-book of Experimental Physiology for Students of Medicine, Dr. N. H. Alcock, Dr. F. O'B. Ellison, 97
Elementary Photo-micrography, Walter Bagshaw, J. E. Barnard, 97
John Dee (1527–1608), Charlotte Fell Smith, Sir T. E. Thorpe, C.B., F.R.S., 121
The Precious Metals, comprising Gold, Silver, and Platinum, Dr. T. Kirke Rose, 122
Beautiful Flowers and How to Grow Them, Horace J. Wright and Walter P. Wright, 123
The Evolution of British Cattle and the Fashioning of Breeds, Prof. James Wilson, 124
A General Geography of the World, H. E. Evans, 125
The Oxford Geographies, 125; the Practical Geography, J. F. Unstead, 125; the Elementary Geography, F. D. Herbertson, 125; a First Physiography, Europe, excluding the British Isles, 125
Cambridge County Geographies, Norfolk, W. A. Dutt, Suffolk, W. A. Dutt, Hertfordshire, R. Lydekker, Wiltshire, A. G. Bradley, 125
By Road and River, a Descriptive Geography of the British Isles, E. M. Wilmot-Buxton, 125
A Systematic Geography of the British Isles, G. W. Webb, 125
Highways and Byways in Middlesex, W. Jerrold, 125
Growls from Uganda, Critolaos, 125
Weather Indicator, 126
Science and Singing, Ernest G. White, 126
Butterflies and Moths of the United Kingdom, Dr. W. Egmont Kirby, 126
Antiquities of the Mesa Verde National Park, Spruce-tree House, Jesse Walter Fewkes, 130
Tuberculosis among Certain Indian Tribes of the United States, Ales Hrdlička, 130
Studies in Fossil Botany, Dr. Dukinfield H. Scott, F.R.S., Prof. A. C. Seward, F.R.S., 151
A Treatise on Zoology, Vertebrata Craniata, Cyclostomes and Fishes, E. S. Goodrich, F.R.S., 152
Sylviculture, Albert Fron, Prof. W. R. Fisher, 153
Exercises in Physical Chemistry, Dr. W. A. Roth, 153
Laboratory Methods of Inorganic Chemistry, Heinrich Biltz and Wilhelm Biltz, 153
Macmillan's Practical Modern Geographies, 154
A Geography of the British Isles, Dr. A. Morley Davies, 154
Practical Exercises in Geography, B. C. Wallis, 154
Carburettors, Vaporisers, and Distributing Valves used in Internal Combustion Engines, E. Butler, 155
Cotton-spinning Calculations, W. S. Taggart, 155
Proceedings of the Aristotelian Society, Prof. A. E. Taylor, 155
An Introduction to the Study of Biology, J. W. Kirkaldy and I. M. Drummond, 156
Mosquito or Man, Sir Rubert Boyce, F.R.S., 158
Traité de Géologie, les Périodes géologiques, Prof. Émile Haug, 181
Illustrations of Cyperaceæ, Charles Baron Clarke, F.R.S., 182
Das Pflanzenreich, Cyperaceæ-Caricordeæ, Georg Kükenthal, 182
Das Pflanzenreich, Phytolaccaceæ, Hans Walter, 182
A Hand-list of the Genera and Species of Birds, R. Bowdler Sharpe, 183
Darwinism and Modern Socialism, F. W. Headley, A. E. Crawley, 183
Semmelweis, his Life and Doctrine, Sir William J. Sinclair, 184
The Elements of Non-Euclidean Geometry, Dr. J. L. Coolidge, 185
Über Farbenphotographie und verwandte naturwissenschaftliche Fragen, Prof. Otto Wiener, 185
Outlines of Chemistry, with Practical Work, Dr. H. J. H. Fenton, F.R.S., Prof. A. Smithells, F.R.S., 186
The Kea, a New Zealand Problem, G. R. Marriner, 186
How to Study the Stars, L. Rudaux, 187
How to Identify the Stars, Dr. Willis I. Milham, 187
Scientific Nutrition Simplified, Goodwin Brown, 187
A Barometer Manual for the Use of Seamen, 187
Cows, Cow-houses, and Milk, G. Mayall, 188
The Oxford Geographies, 188; the Elementary Geography, F. D. Herbertson, 188
Cambridge County Geographies, Gloucestershire, Herbert A. Evans, Westmorland, Dr. J. E. Marr, F.R.S., 188
Ethnology of the Yuchi Indians, Frank G. Speck, 191
Malaria and Greek History, W. H. S. Jones, Prof. R. T. Hewlett, 192
The History of Greek Therapeutics and the Malaria Theory, E. T. Withington, Prof. R. T. Hewlett, 192
Dea Febris, a Study of Malaria in Ancient Italy, W. H. S. Jones, Prof. R. T. Hewlett, 193
Annual Report on the Distribution of Grants for Agricultural Education and Research in the Year 1907–8, 193
Jahresbericht der Vereinigung für angewandte Botanik, 202
The Cambridge Natural History, Crustacea, G. Smith, W. F. R. Weldon; Trilobites, H. Woods; Introduction to Arachnida, and King-crabs, A. E. Shipley; Eurypterida, H. Woods; Scorpions, Spiders, Mites, Ticks, &c., C.

Warburton; Tardigrada (Water-bears), A. E. Shipley; Pentastomida, A. E. Shipley; Pycnogonida, Prof. D'Arcy W. Thompson, 211
The Theory of the Construction of Tables of Mortality and of Similar Statistical Tables in Use by the Actuary, G. F. Hardy, 212
The Engineering of Ordnance, Sir A. Trevor Dawson, 213
The Vegetable Proteins, Dr. Thomas B. Osborne, 214
Clinical Commentaries deduced from the Morphology of the Human Body, Prof. Achille De-Giovanni, 214
Pronunciation of Plant Names, 215
Botany, Prof. J. Reynolds Green, F.R.S., 215
Essentials of Botany, Joseph Y. Bergen, 215
Geology in the Field, 215
Who's Who, 216
Who's Who Year Book for 1910, 216
The Writers' and Artists' Year Book, 1910, 216
The Englishwoman's Year Book and Directory, 1910, 216
Hazell's Annual for 1910, 216
The New Physics: Sound, Joseph Battell, 216
The Great Wall of China, Dr. William Edgar Geil, 220
Illustrations of African Blood-sucking Flies, other than Mosquitoes and Tsetse-flies, E. E. Austen, 241
Lehrbuch der Paläozoologie, Prof. E. Stromer von Reichenbach, Dr. Ivor Thomas, 242
A Manual of Forensic Chemistry, dealing especially with Chemical Evidence, its Preparation and Adduction, William Jago, C. Simmonds, 242
The Morphia Habit and its Voluntary Renunciation, Dr. Oscar Jennings, 243
Practical School Gardening, P. Elford and Samuel Heaton, Dr. E. J. Russell, 243
The Alternating-current Commutator Motor and the Leakage of Induction Motors, Dr. Rudolf Goldschmidt, Prof. Gisbert Kapp, 244
Practical Microscopy, F. Shillington Scales, 245
Erosion of the Coast and its Prevention, F. W. S. Stanton, 245
The Evolution of the Sciences, L. Houllevigne, 245
History of Astronomy, Prof. G. Forbes, F.R.S., 245
Wild Flowers and Trees of Colorado, Dr. F. Ramaley, 246
The Historic Thames, Hilaire Belloc, 246
The Heart of England, E. Thomas, 246
Beasts and Men, being Carl Hagenbeck's Experiences for Half a Century among Wild Animals, 247
Review of Norwegian Fishery and Marine Investigations, 1900–8, 249
Essays in Eugenics, Sir Francis Galton, F.R.S., 251
The Mendel Journal, 251
Biometrika, 251
Some Desert Watering Places in South-eastern California and South-western Nevada, Walter C. Mendenhall, 262
Water Supply Investigations in the Yukon-Tanana Region, C. C. Covert, C. E. Ellsworth, 262
Surface Water Supply of Nebraska, J. C. Stevens, 262
Geology and Water Resources of the Harvey Basin Region, Oregon, Gerald A. Waring, 262
Papers on the Conservation of Water Resources, 262
The Ether of Space, Sir Oliver Lodge, F.R.S., 271
Nouvelle Méthode de Prévision du Temps, Gabriel Guilbert, 271
Text-book of Embryology, Dr. Frederick R. Bailey, Adam M. Miller, Dr. Francis H. A. Marshall, 272
Modern Problems in Psychiatry, Prof. E. Lugaro, 273
The Autobiography of Nathaniel Southgate Shaler, with a Supplementary Memoir by his Wife, Prof. Grenville A. J. Cole, 274
Geometry for Beginners, C. Godfrey, A. W. Siddons, 275
The School Geometry, W. P. Workman and A. G. Cracknell, 275
Coordinate Geometry, H. B. Fine and H. D. Thompson, 275
Exercise Papers in Elementary Algebra, Rev. E. M. Radford, 275
Problem Papers in Mathematics, R. C. Fawdry, 275
Ant Communities and How They are Governed, Dr. H. C. McCook, 276
Sextant Errors, Thos. Y. Baker, 276
The British Journal Photographic Almanac, 1910, 277
Outlines of Bacteriology (Technical and Agricultural), Dr. David Ellis, Prof. R. T. Hewlett, 277
A Descriptive Catalogue of the Dobrée Collection of European Noctuæ, 277
The Human Race, its Past, Present, and Probable Future, J. Samuelson, 277
The Heart of the Antarctic, being the Story of the British Antarctic Expedition, 1907–9, Sir E. H. Shackleton, C.V.O., Prof. J. W. Gregory, F.R.S., 280
In the Grip of the Nyika: Further Adventures in British East Africa, Lieut.-Col. J. H. Patterson, D.S.O., Sir H. H. Johnston, G.C.M.G., K.C.B., 283
The American Federation of Teachers of the Mathematical and the Natural Sciences, G. F. Daniell, 284
Report of a Magnetic Survey of South Africa, Prof. J. C. Beattie, 285
Three Years in Tibet, the Shramana Ekai Kawaguchi, Lieut.-Col. L. A. Waddell, 301
La Géologie générale, Prof. Stanislas Meunier, Prof. Grenville A. J. Cole, 302
Évolution géologique de la Terre et ancienneté de l'Homme, Alphonse Cels, Prof. Grenville A. J. Cole, 302
The Fundamental Principles of Chemistry, Prof. W. Ostwald, 303
Scientific and Biological Researches in the North Atlantic, conducted by the author on his Yachts The Walwin and The Silver Belle, Dr. R. Norris Wolfenden, 304
The Family and the Nation, a Study in Natural Inheritance and Social Responsibility, W. C. Dampier Whetham, F.R.S., and Catherine Durning Whetham, 305
Indian Woods and their Uses, R. S. Troup, 305
A Survey and Record of Woolwich and West Kent, 306
The Flora of the Dutch West-Indian Islands, J. Boldingh, 307
Weather Forecasting by Simple Methods, F. S. Granger, 307
The Life of Major-General Sir Charles William Wilson, Royal Engineers, K.C.B., K.C.M.G., F.R.S., Colonel Charles M. Watson, K.C.M.G., 311
L'Organisation syndicale et Technique en Allemagne, M. E. Leduc, C. Simmonds, 313
Third Annual Report of the Committee of Control of the South African Central Locust Bureau, 314
Lord Kelvin's Early Home, Mrs. Elizabeth King, 331
Les Zoocécidies des Plantes d'Europe et du Bassin de la Méditerranée, Dr. C. Houard, 333
Électricité Agricole, A. Petit, 334
Physiography for Schools, R. D. Salisbury, 335
An Atlas of Absorption Spectra, Dr. C. E. K. Mees, 336
Physiology of Man and other Animals, Dr. Anne Moore, 336
Deutsche Südpolar-Expedition, 336
Les Progrès récents de l'Astronomie (1908), Prof. Paul Stroobant, 336
Leisure Hours with Nature, E. P. Larken, 341
The Wood I Know, the Meadow I Know, the Stream I Know, the Common I Know, 341
The Ruskin Nature Reader, 341
Cyclopedia of American Agriculture, Dr. E. J. Russell, 361
Sir John Banks, the "Father of Australia," J. H. Maiden, W. B. Hemsley, F.R.S., 362
Vergleichende Anatomie der Wirbelthiere, Dr. Robert Wiedersheim, 362
A Course of Practical Chemistry, for Medical, Dental, and General Students, A. Beresford Ryley, 363
Introduction to Practical Chemistry, for Medical, Dental, and General Students, A. M. Kellas, 363
First Stage Inorganic Chemistry (Practical), H. W. Bausor, 363
Bathy-orographical Wall Maps of the Pacific, Atlantic, and Indian Oceans, 364
The Practical Management of Sewage Disposal Works, W. C. Easdale, 365
Das Reich der Walken und Niederschläge, Prof. Dr. Carl Kassner, 365
Astronomische Abhandlungen der Hamburg Sternwarte in Bergedorf, 365
Trans-Himalaya, Sven Hedin, 367
Nature Photography for Beginners, E. J. Bedford, 371
Surface Water Supply of the United States, 1907–8, Part ii., South Atlantic Coast and Eastern Gulf of Mexico, M. R. Hall and R. H. Bolster, 379

Underground Water Resources of Connecticut, Herbert E. Gregory, 379
Occurrence of Water in Crystalline Rocks, E. E. Ellis, 379
Die Glasindustrie in Jena, ein Werk von Schott und Abbe, 391
The Natural History of British Game Birds, J. G. Millais, 392
The Manufacture of Leather, H. Garner Bennett, 393
Liverpool Marine Biological Committee's Memoirs, XVIII., Eledone, Annie Isgrove, XIX., Polychæt Larvæ, F. H. Gravely, 393
Applied Mechanics, embracing Strength and Elasticity of Materials, Theory and Design of Structures, Theory of Machines and Hydraulics, Prof. David Allan Low, 394
Strength of Material, an Elementary Study prepared for the Use of Midshipmen at the U.S. Naval Academy, H. E. Smith, 394
Stresses in Masonry, H. Chatley, 394
Animals and their Ways, E. Evans, Dr. C. Gordon Hewitt, 395
The Hedge I Know, Dr. C. Gordon Hewitt, 395
The Pond I Know, Dr. C. Gordon Hewitt, 395
Butterflies and Moths Shown to the Children, Janet H. Kelman and Rev. Theodore Wood, Dr. C. Gordon Hewitt, 395
Nests and Eggs Shown to the Children, A. H. Blaikie and J. A. Henderson, Dr. C. Gordon Hewitt, 395
The Backwoodsmen, Charles G. D. Roberts, Dr. C. Gordon Hewitt, 395
Recent Advances in Physical and Inorganic Chemistry, Dr. A. W. Stewart, 396
The Elements of Mechanics of Materials, C. E. Houghton, 396
Experimental Mechanics for Schools, F. Charles and W. H. Hewitt, 396
Air and Health, R. C. Macfie, 397
Die Arve in der Schweiz, Dr. M. Rikli, 399
Artificial Manures, their Chemical Selection and Scientific Application to Agriculture, M. George Ville, Dr. E. J. Russell, 421
Handbuch der Anorganischen Chemie, 422
The Grizzly Bear, W. H. Wright, 423
The Animals and their Story, W. P. Westell, 423
Man and the Universe, Sir Oliver Lodge, F.R.S., 424
Descriptive Geometry, Prof. V. T. Wilson, 425
Practical Arithmetic for Schools, W. G. Borchardt, 425
The Calculus and its Applications, R. G. Blaine, 425
A Primer of Statistics, W. Palin Elderton and Ethel M. Elderton, 426
All About Ships and Shipping, Commander R. Dowling, R.N.R., 426
Van Nostrand's Chemical Annual, 1909, 426
The Interpretation of Topographic Maps, R. D. Salisbury and W. W. Attwood, 430
A History of the Oxford Museum, Dr. H. M. Vernon and K. Dorothea Vernon, 432
On the Distribution of the Fresh-water Eels (Anguilla) throughout the World, (1) Atlantic Ocean and Adjacent Regions, Johs. Schmidt, 433
The Collected Papers of Joseph, Baron Lister, 451
Nel Darien e nell' Ecuador, Dr. E. Festa, 452
The Animals of Australia, A. H. S. Lucas and W. H. Dudley Le Souëf, 453
Elements of Machine Design, Dr. S. Kimball and J. H. Barr, 454
An Introduction to the Geology of Cape Colony, Dr. A. W. Rogers and A. L. Du Toit, 454
The Romance of Modern Chemistry, Dr. J. C. Philip, 455
Hayward's Botanist's Pocket-book, G. C. Druce, 455
Yorkshire Type Ammonites, 455
Klimatographie von Österreich, Dr. H. v. Ficker, 455
The Scholar's Book of Travel, 456
Cambridge County Geographies, Cambridgeshire, Prof. T. McKenny Hughes, F.R.S., and Mary C. Hughes, 456
Wanderings among South Sea Savages and in Borneo and the Philippines, H. Wilfred Walker, 459
Warming-Johansen, Lehrbuch der algemeinen Botanik, 481
Text-book of Egyptian Agriculture, 482
La Vallée de Binn (Valais), Léon Desbuissons, 482
Text-book on Hydraulics, G. E. Russell, 483
L'Électricité considérée comme Forme de l'Énergie, Lieut.-Colonel E. Aries, 484
Lehrbuch der Physik, E. Grimsehl, 484
Elements of Physics for Use in High Schools, H. Crew, 484
Light, Prof. R. C. Maclaurin, 484
Genetic Psychology, E. A. Kirkpatrick, 485
The Psychology of Thinking, Dr. J. E. Miller, 485
Das Kaninchen, 485
The Irish Fairy Book, Alfred Perceval Graves, Rev. John Griffith, 486
Space and Spirit, R. A. Kennedy, 486
Introduction to the Preparation of Organic Compounds, Prof. Emil Fischer, 486
Agriculture in the Tropics, Dr. J. C. Willis, 492

Revis (Mr.), Nature of the Cellular Elements present in Milk, 257
Reynolds (Prof. S. H.), Igneous and Associated Sedimentary Rocks of the Glensaul District (County Galway), 387
Reynolds (W. D.), on a Practical Theory of Elliptic and Pseudo-elliptic Arches, with Special Reference to the Ideal Masonry Arch, 268

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"*To the solid ground*
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

THURSDAY, NOVEMBER 4, 1909.

MODERN WELDING.

Welding and Cutting Metals by Aid of Gases or Electricity. By Dr. L. A. Groth. Pp. xvi+281. (London: A. Constable and Co., Ltd., 1909.) Price 10*s.* 6*d.* net.

THE art of welding iron is very old, probably as old as the production of the metal from its ores. Previous to the nineteenth century the art of forging and welding iron reached a high stage of development. Then came the cast-iron period, which for a time usurped the place of the forged metal. But during the last half-century, owing to improved and less costly methods of production and the introduction of machines which can make forgings of a size far greater than can be worked by a smith, new methods of welding have become necessary. Welding of the metals has kept pace with the improvements in metallurgy, and a great part of it is now carried out by fusion; consequently, joins of almost any thickness can now be made, whereas by the method of hand hammering the size and thickness of the joins was very limited.

The book before us deals with the welding of metals mainly by the newer methods which have been made possible by the advance in electrical science and by the use of reducing flames of high temperature, such as hydrogen and acetylene. But not only can high-temperature flames be employed for welding; they can also, by altering the conditions, be used for cutting thick plates of metal. Whereas, however, the welding is carried out by means of flames containing an excess of a reducing gas, the cutting is done by means of flames rich in oxygen.

The book commences with a short introduction explaining the nature of a weld. Chapter ii. is headed "Gases and Sources for their Generation." One hardly knows what to make of this chapter; if it is written for the novice it is useless, if written for the chemist unnecessary. We are told, in the first place, "it has been known for ages that matter is capable of existing in three physical states: the solid state, the liquid state and the gaseous state."

Further on there is an historical account of the manufacture of calcium carbide and of the preparation of acetylene. It is a pity that this part of the book is not written in a manner to help the welder or cutter, and is not always accurate. What, for example, does this mean?

> (Hydrogen) "is usually prepared by the action of zinc or iron on a solution of hydrochloric or sulphuric acid. All metals which readily decompose water when heated readily furnish hydrogen on a similar treatment. Many other acids may be used, *but none cut more readily*. In all cases the action consists in the displacement of the hydrogen . . . and if the acid is not one which can enter into reaction with the displaced *nitrogen*, the latter is evolved as a gas."

Poor novice! Again, hydrogen was not liquefied by Cailletet on December 30, 1877.

From chapter iii. and onward the book is interesting and instructive. Welding and the different systems employed are described—thus autogenous, or the union of the metals by direct fusion; under this we get alumino-thermic processes, electric welding, welding with compressed gases. Heterogeneous, in which a foreign metal or alloy is employed, which has a lower melting point than the metals to be joined.

The welding of aluminium, which is similar to lead burning, is described, and illustrations are given to show that, as a rule, the tensile strength of a welded bar is greatest at the weld, or, at any rate, breaking does not take place at this position. The alumino-thermic process is well described, and two interesting diagrams showing the mending of cracks in the stern frame of a steamer are shown.

A considerable amount of space is devoted to electric welding, which has been found so useful in the welding of pipes and tubes; very interesting illustrations showing the joining of pipes to form T's and other unions are given.

Chapter iv. deals with blow-pipes of various design which are used for different purposes. We are not particularly impressed with the insertion of advertising letters in chapter v. This chapter deals with the welding of sheet-iron, and various methods are described. But surely it should not be necessary to print letters from the Public Works Department of Perth, W. Australia, and from other bodies, writing in appreciative terms of a certain process which, as we are not advertising it, we need not mention. To our mind, in book-writing the author should use his own judgment, which may or may not be influenced by letters of recommendation, but it says little for his analytical skill if he finds it necessary to print the letters.

The part of the book dealing with the welding and cutting of metals is extremely interesting, and illustrates the great advance which has recently been made in this direction. In all autogenous processes a reducing flame which prevents the formation of oxides is a *sine qua non*; but when a flame is to be used for cutting purposes the reverse is the case. Most metals, when heated to a sufficiently high temperature, will burn in oxygen. This property is made use of in cutting steel, for example. An oxy-hydrogen flame is caused to impinge upon the metal, and at the same time an auxiliary blow-pipe directs oxygen gas upon the heated surface; immediate combustion ensues. The stream of oxygen is sufficiently powerful to drive away the oxide as it is formed, and the cutting progresses very rapidly. For example, an armour plate 6·3 inches thick was thus cut to a length of 1 metre in ten minutes. At Bremen a similar process has been employed for cutting up and scraping ships.

The book is suggestive, useful, and will, we hope, enjoy a large circulation in spite of the few errors here pointed out, and when the second edition is being prepared we trust the author will take notice of our friendly criticism.

F. M. P.

PROBLEMS IN NUTRITION.

Volksernährungsfragen, and *Kraft und Stoff im Haushalte der Natur.* By Prof. Max Rubner. Pp. iv+143 and 181 respectively. (Leipzig: Academische Verlagsgesellschaft, 1908, 1909.)

THESE two little books contain three useful and readable essays on those nutritional problems to which Prof. Max Rubner has directed most of his research work. The first of the above-mentioned books contains two of these, and they treat of the minimum protein requirement of man and of diet of the poor respectively. The first question has within recent years been brought prominently before the scientific world, as well as the public at large, by the work of Chittenden and others, who argue from their experiments that, because they themselves have been able for limited periods to maintain their health and equilibrium on an amount of protein which is far below the usually accepted Voit minimum, therefore all men should permanently reduce their intake of protein to the same low level. Those who believe that the minimum is also the optimum would do well to read and consider carefully the Berlin professor's judicial commentary on their views.

What most strikes the reader is the extraordinary complexity of the problem. One factor, however, is absent, and that is the effect of work and rest, for this causes practically no effect on the metabolism of protein matter; but the question is sufficiently complex without this. There is between different people an enormous variation in what one may term their metabolic habits, so that any hard and fast rule is impossible. The mere body weight is not an important element, although, naturally, the heavier a man the more protein will he require. If this were all, it would be easy to adapt the dosage to the body weight; but the difference is deeper than this; to mention one point only, it is shown that, as a rule, the thin person requires more protein to maintain nitrogenous equilibrium than the corpulent. It must have been a matter of common observation that the stoutest people are not the biggest eaters. Another complicating factor is what one eats with the protein, and also the kind of protein one ingests. It is shown that on a potato diet, for example, the minimum necessary to maintain nitrogenous equilibrium is less than with any other of the diets adopted. We have further to take into account the presence, in most foods, of nitrogenous substances which are not protein, but which, nevertheless, have to be reckoned with.

The second essay, on the diet of the poor (agricultural labourers and the like), emphasises very clearly one reason why a low protein intake brings the consumer dangerously near to the margin. It is shown beyond question that such a diet renders people much more prone to take infectious diseases, and there is a general lowering of the powers of resistance. Considering that the bulk of the population consists of those who are not well to do, this becomes a matter of national importance, and it is the duty of the State to interfere. Prof. Rubner appears to think that legislative measures should be adopted. We can see, however, that the difficulty of legislating on such a matter is very great; but at least the people should be educated on the question of feeding rationally, especially where children are concerned. Anyone with any experience of hospital patients knows that ignorance, in addition to poverty, is at the bottom of most of the conditions of malnutrition which meet us at every turn. Ignorance, moreover, is not confined to the poor in regard to this most important question.

The third essay, which occupies the second volume, is a summary of Prof. Rubner's work on nutrition generally; it is written in a more popular manner than most of his publications, and a distinct philosophical vein runs through it. The chemical events which occur in the living body fall mainly into two categories—(1) those due to the activity of enzymes; in these there is but little transformation of energy; and (2) those which may roughly be described as combustion, and from which the energy of living and doing is derived. It is the second class of chemical changes to which Prof. Rubner has mainly directed his attention, and it is to him, in particular, that we owe the experimental proof that the law of conservation of energy applies to the living cell as well as to the world of inorganic matter. The law of the conservation of energy is so universal that one might, perhaps, have assumed it would hold for living as well as for lifeless material. But the scientific mind assumes nothing without direct proof; we have no right to assume beforehand that some other law might not be found operating in the organic world. The crude calorimetric researches of Lavoisier and the early pioneers of this subject certainly showed great discrepancies between the results obtained and those calculated from the energy value of the diets employed; but as technique has improved so has it been shown that all such discrepancies were the result of imperfection in the methods used. For the improvements in method, and the patient working out of the problem as well as the final demonstration of the truth of the great law of energy conservation in the world of life, there is no one to whom we owe more than to Prof. Rubner himself.

W. D. H.

COLOUR MANUFACTURE.

A Treatise on Colour Manufacture. A Guide to the Preparation, Examination, and Application of all the Pigment Colours in Practical Use. By George Zerr and Dr. R. Rübencamp; authorised English edition by Dr. Charles Mayer. Pp. xiv+605. (London: C. Griffin and Co., Ltd., 1908.) Price 30*s.* net.

THIS volume is the most complete publication on colour manufacture which has yet been produced in English. After dealing with the general preparation of materials, and describing the various types of grinding and sifting machines, in part ii. the manufacture of artificial mineral colours in dealt with in a very thorough manner, although in certain details inaccuracies are, as is to be expected, to be found.

Part iii. deals with the raw materials used in colour making, their properties, adulterations, and tests for purity. This section should prove very valuable in many colour works where the raw materials are bought in large quantities, and reliable information of this kind will enable them to be readily examined to test their purity.

The natural mineral colours and black pigments are then dealt with, and following upon this is a description of organic colouring materials and their utilisation in making lake pigments. The first section deals with natural organic substances, while the second section deals with the application of the coal tar colours to the manufacture of lakes. This section should prove of considerable value to colour makers, as it contains a scientific classification of the coal tar derivatives, and so reveals the principles upon which such lakes must be prepared. It is, of course, impossible that such a treatment of the subject should be up to date, as fresh coal tar products and fresh methods of obtaining trustworthy lakes from them are constantly being produced, but a study of these chapters will give the student a thorough grip of the principles underlying the manufacture of these lakes, and some interesting information will be found at the end of this section of the book on the reactions of the more important lakes from artificial colouring materials, which should be of use to those who wish to match samples that have been submitted. There is also a brief account of the use of pigments in different ways which, while very general in character, contains some very interesting information.

In the appendix will be found a table of solubilities of many of the salts used by the colour maker, in cold and in hot water, which should prove of practical value, while there are in addition specific gravity tables for a certain number of these salts which should also be of use.

As has been stated, there are certain errors in detail to be noted, more especially in connection with the finer colours which are used for artists' purposes, and two of these which happened to have caught the eye of the reviewer may be pointed out. On page 154, Indian yellow is incorrectly described as being the same thing as cobalt yellow, Indian yellow being a preparation of euxanthic acid obtained from India, and cobalt yellow is described as being not very fast to air and light, while, as a matter of fact, it is one of the most permanent pigments to be found in the artist's palette. Again, under blue colours on p. 203, cobalt blue is spoken of as being now of no technical value. Considering the very large use of cobalt blue by artists and for superior decorative purposes, this statement is scarcely justifiable. The description of the manufacture of cadmium yellows is also very far from complete, and no doubt other similar small errors could be found throughout the book, and are inevitable in a work of this kind.

A more serious defect is one which is to be found in a great many works on colour manufacture. While elementary information on qualitative and quantitative analysis is published—see, for instance, the discussion of the methods of volumetric analysis on p. 343—information which it is only right to suppose is perfectly familiar to the modern colour maker and colour chemist, and simple qualitative tests are given which are to be found in all elementary books on qualitative analysis, little information is supplied as to the complete analysis of modern pigments. Such information would be of value even to the skilled analyst, who, when he comes across some pigment, wishes to know the probable defects to look for, the kinds of adulteration likely to be present, and the most rapid manner of handling with a view to making a sufficiently complete analysis for practical purposes. Some attempt to deal with this problem was made by Hurst in his book on pigments, but a more complete scientific handling of the subject is very much required.

In conclusion, this book may be safely recommended to all those interested in colour manufacture, as containing a great deal of useful and valuable information brought together in a clear and practical form.

UNIVERSITY ADMINISTRATION.

University Administration. By Charles W. Eliot. Pp. 266. (London: Constable; Boston and New York: Houghton, Mifflin and Co., 1909.) Price 6*s.* net.

UNIVERSITY politics has long been a current phrase, and questions of university government and policy have been increasingly discussed of recent years; yet, in spite of the rapid increase in the number of the English universities, and of the many interesting experiments in organisation which they embody, there has so far been no comprehensive treatise written in this country upon university administration. The gap is now filled, though from the other side of the Atlantic, by the late president of Harvard, who has condensed his thirty-nine years of experience as the ruler of the most famous of the American universities into a book which will long rank as the standard authority on the subject. Written with admirable clearness and precision, it states and discusses sensibly and practically problem after problem with which English readers are familiar in newspaper discussions on university reform, but which it is not easy to see in their wider bearings.

The book is divided into six chapters, which deal successively with university trustees, inspecting and consenting bodies, faculties, the elective system, methods of instruction, concluding with a chapter on the social organisation of a university, the position of the president, and several questions of general administration.

The most novel and interesting chapter in the book is undoubtedly that on the elective system, the introduction of which at Harvard has been the main feature of President Eliot's *régime*, and which he is at pains to explain and defend. He describes it as a "carefully arranged scheme of numerous courses of instruction which are open to the choice of students under rules partly artificial but chiefly natural and inevitable." Its effect is to give the individual student, not unlimited, but still far more extensive opportunities of "following his bent" in the choice of his university course than he gets under the fixed courses in subjects or groups of subjects which are usual in English universities. President Eliot claims that, if strictly administered, it satisfies the needs of serious students with intellectual initiative of their own who are apt to feel cramped by a rigid college course, while for the mediocre and unambitious it offers the "only chance of experiencing an intellectual awakening while in college." At the same time, it gives every teacher the precious privilege "of having no student in his class who has not chosen to be there." Its main difficulty is, of course, that it is very much more expensive than the "prescribed" system.

President Eliot's two chapters on university government will be read with interest in this country, especially in view of Lord Curzon's recent book on the government of Oxford, which, written from a wholly different standpoint, affords a striking illustration of some of Prof. Eliot's views. Harvard, which President Eliot regards as "the university with the most fortunate organisation in the country," is governed by a body of trustees, seven in number, controlled by a body of thirty overseers, elected by the whole body of Alumni, who exercise, through visiting committees and otherwise, powers of inspection and veto. The overseers thus play the part of the whole body of M.A.'s of Oxford and Cambridge, only with vastly increased efficiency, because they are a representative committee, and not an unorganised mob periodically assembled by a whip. Lord Curzon's recent proposal to constitute at Oxford a new finance board of eight or ten members, partly non-residents, to exercise a general control over college and university finance, is thus clearly on the lines of the American boards of trustees; but President Eliot's book throws no light, of course, on the main difficulty of university organisation in the older universities, the relation between the university and the wealthy and autonomous collegiate corporations which have grown up in its midst.

PROBLEMS OF IMMORTALITY.

Unsterblichkeit: eine Kritik der Beziehungen zwischen Naturgeschehen und menschlicher Vorstellungswelt. By Hermann Graf Keyserling. Pp. iv+349. (München: J. F. Lehmanns Verlag, 1907.)

COUNT KEYSERLING has chosen a subject upon which the views even of a dull man are frequently interesting, if only as a "document," and he has treated it in a manner that makes his book a notable contribution to its serious study. He is broad-minded and well informed; he develops his argument lucidly and consecutively, and he illuminates it with considerable literary grace.

An examination of the data of the famous argument for immortality which appeals to the consensus of mankind, *semper et ubique*, shows that, in reality, it gives no support to any specific form of the doctrine. The concepts of future existence described by ethnologists and historians differ enormously, not only in detail, but even in principle. If, then, we continue (as does the author) to attach importance to the consensus, we must regard it as giving a merely formal guarantee of some kind of post-vital permanence which it is impossible to specify. To be assured that it has this value requires a critical examination of the nature and functions of faith (*Glaube*). Faith is to be identified neither with an unverified belief in matters that may eventually become the objects of certain knowledge, nor with a confidence in things of which certain knowledge is, by the nature of the case, impossible; it is a specific activity of the soul in which it fastens upon, or recognises, the ultimate assumptions of a causal or logical nexus. It is by faith that I recognise the validity of a geometrical axiom, the existence of God, the reality of the objective world, and the correlated reality of my own subjective existence. I may be mistaken in the particulars of my assumptions under any one of these heads—as I am, for instance, in perceptual illusion—but in no case can my final certainties rest upon any other ground than faith. The possibility of error in the contents to which faith attaches merely illustrates its purely formal character as an epistemological function. It follows from this definition that faith is not a temporary phase, but a permanent and essential constituent of the human movement along the lines both of thought and of action. There is, in fact, a "conservation of faith" within the subjective world analogous to the conservation of energy in the physical world—the one regulating our recognition of Being much in the same way that the other regulates our recognition of Becoming.

Examining the character and contents of human experience by the aid of this theory of faith, the author finds that it yields no support to the belief in a continued personal existence. On the contrary, he detects in the moral consciousness a recognition that the permanent element in us is an Entelechy that produces our "personality" as a purely temporary phenomenon, and will in due time pass upon its way. It draws from an underlying sea of infinite, unimaginable Being, and our individualities are, as it were, merely the waves in which, from moment to moment, the ceaseless movement of this sea expresses itself.

It is unlikely that the reader will be able to agree with all Count Keyserling's views; in particular, he will probably feel that the concept of faith as a purely formal function is by no means clear. His dissatisfaction with this part of the argument will not, however, interfere with his appreciation of the ability with which the author has conducted his inquiry and of the stimulating manner in which he has presented his results.

T. P. N.

DESCRIPTION OF NEW MINERALS.

Second Appendix to the Sixth Edition of Dana's System of Mineralogy. By Edward S. Dana and William E. Ford. Pp. xii+114. (New York: John Wiley and Sons; London: Chapman and Hall, Limited, 1909.) Price 6s. 6d. net.

THE debt of gratitude that mineralogists, and, indeed, all interested in the physical and chemical characters of the inorganic products of nature, owe to the Danas, *père et fils*, is immense, and can scarcely be realised owing to the human propensity to take for granted all that is provided to hand. The task of compiling such a compendium is without ending. Mineralogy, like all branches of science, does not stand still, and no sooner has an edition appeared than it begins to need expansion and revision. The larger a work of this character becomes, the greater is the difficulty in bringing out fresh editions at short intervals; yet something must be done if pace is to be kept with the growth of mineralogical science. In the present instance the problem has been solved by the issue of a series of appendices. The last edition, which was the sixth, of the "System of Mineralogy," was produced by Prof. E. S. Dana in 1892; the first appendix was issued in 1899, and now, ten years later, the second appendix has appeared.

In the present volume the same plan has been followed as in the first appendix. It opens with a list of the principal works that have been published within the period dealt with, and a list of new mineral species classified according to the arrangement of the system. The rest of the book is occupied with a concise but complete description of the important characters of the new minerals, such as the crystallographical and optical constants, the values of the principal angles, the colour, the specific gravity, the chemical composition and the response to the ordinary reagents, and the locality whence they were obtained; and, further, with an abstract of work that has been done on species previously known. The alphabetical arrangement renders it easy to look up any species, and the reference to the original paper, which is in all cases given, enables the information to be traced to the source. We regret to learn from the preface that the continuous strain proved too much for Prof. Dana, and his breakdown in health nearly three years ago compelled him finally to relinquish the work. Fortunately he had at hand a colleague, Prof. Ford, who was able to complete it for him. Lack of time, however, prevented the course, followed in the "System" and in the first appendix, of re-calculating from the data the crystallographical constants and the important interfacial angles being strictly adhered to.

The rate of discovery of new mineral species shows no sign of abatement, contrary to what might have been expected. The present volume includes about sixty definitely new species. It would, indeed, appear as if any careful search in new or little-known localities could not fail to be fruitful in bringing to light new species. Thus this volume includes descriptions of the interesting results of Dr. Flink's collecting trip to Greenland, many of Mr. Solly's remarkable discoveries in the famous Lengenbach quarry near Binn, the new mercury minerals from Terlingua, and the curious zinc phosphates from the Broken Hill mines, Rhodesia.

G. F. H. S.

OUR BOOK SHELF.

Principles of Reinforced Concrete Construction. By F. E. Turneaure and E. R. Maurer. Pp. x+429. Second edition, revised and enlarged. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1909.) Price 15*s*.

In this edition a considerable number of changes have been made, and much new material has been added. In every case records of experiments have been brought right up to date: this is especially the case in regard to the adherence between the concrete and the reinforcing metal, to the shear strength of beams, and to the strength of columns. The properties of concrete and steel are fully dealt with in chapter ii. The important question of the value of the modulus of elasticity of concrete is discussed in the light of the most recent experiments. The authors are of opinion that for most calculations in regard to strength the value of the modulus should be taken as 2,000,000 lb. per sq. in. The tests on bond by Mr. Withey seem to show that the intensity of the bond per square inch is not affected by the size of the bars, and that the average bond strength as determined by direct tension is much higher than in the case of beam experiments. The difficulty of carrying out these latter tests prevents their more usual adoption. In determining the strength of reinforced-concrete beams, the authors have wisely, for the greater part of the book concerned with this problem, assumed that the stress-strain curve for concrete is practically straight within the limits of the working stresses adopted in practice; in sections 60 to 70 they have, however, deduced a series of flexure formulæ on the assumption that the stress-strain curve is a parabolic arc. In both cases the concrete is assumed not to take any tension. Engineers engaged in structural work involving the use of this material for transverse loads can, therefore, check their results by both sets of formulæ, and thus secure an additional guarantee of the security of their design. Designers learn almost as much from the results of carefully conducted experiments as they do from all the formulæ that fill the various textbooks, and it is satisfactory to find a whole chapter devoted to a description and a discussion of a carefully selected series of rupture tests of both beams and columns.

In dealing with working stresses, the authors discuss the respective advantages and disadvantages of the "working stress" method, and the "factor of safety" method; they incline to the use of the latter in the present case. The whole question is discussed in a thoroughly practical and satisfactory manner in chapter v., especially from the point of view of economy. The last portion of the book deals with the design of reinforced concrete members, and the arrangement of connective details—floors, cross-beams, columns, footings, arches, and retaining walls are all treated in some detail, with numerous excellent dimensioned illustrations—and a complete chapter is given up to the design of chimneys. The fact that this book has already reached a second edition is a proof that it meets a want, and it is also a proof of the rapid spread of the use of reinforced concrete for all kinds of structural work. T. H. B.

The Influence of Heredity on Disease, with Special Reference to Tuberculosis, Cancer, and Diseases of the Nervous System. A Discussion opened by Sir W. S. Church, Bt., K.C.B.; Sir W. R. Gowers, F.R.S.; Dr. A. Latham; and Dr. E. F. Bashford. From the Proc. Roy. Soc. of Medicine, 1909, Vol. II. Pp. xii+142. (London: Longmans, Green and Co., 1909.) Price 4*s.* 6*d.* net.

This volume embodies an important discussion held by the Royal Society of Medicine, and, in view of the importance in determining the influence of heredity as an ætiological factor in the production of disease, the council of the Society has been well advised to publish it separately, as well as in its Transactions, and thus render it accessible to all.

Many eminent names appear and give the weight of their authority to the facts quoted. Sir W. Gowers, Dr. Savage, Dr. Mott, and Dr. Mercier dealt with heredity in connection with nervous and mental diseases; Dr. Latham and Dr. Bashford gave the opening addresses on heredity in tuberculosis and in cancer respectively; Sir John McFadyean dealt with the inheritance of disease among the domestic animals; Prof. Bateson and Mr. Mudge discussed the subject from the biological, and Prof. Karl Pearson from the biometrical, standpoint.

Mendelism naturally occupied a prominent place in the discussion, and great difference of opinion was expressed regarding it. For instance, Prof. Pearson states that "there is no definite proof of Mendelism applying to any living form at present; the proof has got to be given yet."

The pedigrees of many abnormal conditions given by various speakers seem to indicate that much further information is required before we shall be in a position to accept Mendelism, or indeed any other hypothesis of the laws of heredity. In fact, the main results brought out by this discussion would appear to be, first, that medical men and biologists should acquire a working knowledge of statistical methods; and, secondly, that for the next few years a careful collection should be made of pedigrees of abnormal conditions—such as albinism and night-blindness—so that eventually sufficient data may be acquired for proper analysis.

The Campaign against Microbes. By Dr. Étienne Burnet. Translated from the French by E. E. Austin. Pp. xi+248. (London: John Bale, Sons and Danielsson, Ltd., 1909.) Price 5*s.* net.

The author, in our opinion, has missed an opportunity for presenting to the general public an account of the present-day campaign against microbes and microbial diseases. Malaria, Mediterranean and enteric fevers, dysentery, diphtheria, and plague are not referred to, yet how much is now being done to mitigate the ravages of these human pestilences! On the other hand, one-fourth of the book is allotted to cancer, the microbial nature of which at present is, to say the least, discredited; and the essential preventive measures against this disease, so far as we know them, are omitted—*e.g.* the education of the public at once to seek medical advice if a tumour or swelling or abnormal discharge be noticed, and the immediate treatment of all forms of chronic irritation in and after middle life.

Tuberculosis, tetanus, sleeping sickness, enteritis and intestinal microbes, and small-pox and vaccination are the other subjects dealt with. As regards tuberculosis, a great deal is said about the vaccination of cattle, yet how little has this so far been applied practically? Tetanus, again, fearful as it is in individual cases, is not of much importance to the community as a cause of death. In the section on enteritis and intestinal microbes, the sour-milk treatment is rightly extolled, but to the exclusion of other matters, and the section on small-pox is mainly a history of Jenner's discovery. The book, therefore, while interesting and instructive so far as it goes, is disappointing, and seriously wanting as an exposition of the modern crusade against infective diseases.

The translator seems to have done his work well, but might in places have incorporated the results of recent research. R. T. Hewlett.

Brazil in 1909. By J. C. Oakenfull. Pp. 237. (Brazilian Government Commission of Propaganda and Economic Expansion. Paris, 1909.)

A country sixteen times the size of France, with a population barely half as numerous, a country teeming with mineral wealth, favoured with majestic river-systems, and climates capable of producing everything needed by man, boasting, too—at least on paper—a body of laws unsurpassed anywhere in their broadminded liberality—such is the theme Mr. Oakenfull has undertaken to expound. An immense undertaking, indeed, were it set out in all possible fulness of detail; but when compressed into some two hundred pages, requiring a tactful hand to give each subject its due space and no more. This task of selection has been carried out well. Publicists, financiers, miners, pastoralists, agriculturists, and tourists will all find their requirements catered for. The best chapters are those devoted to mineralogy and applied botany; but, as so often happens when the writer is not an expert botanist, a sad hash is made of some of the Latin names. For instance, *Cattleya amethyst oglobossa* is not in the "Index Kewensis," nor do botanists talk of *violaceas* or *bromeliaceas*. For his next edition Mr. Oakenfull should enlist the services of a botanist; he would also do well to revise his composition in places. Moreover, his account of the climate seems to us rather too optimistic; when the heat is moist, in Brazil as in all tropical countries, the conditions are apt to be very enervating. To the student of social phenomena the most interesting part of the book is that dealing with the rapid advances made under the Republic. The inducements to colonists, it may be added, are simply astounding in their liberality. S. M.

LETTERS TO THE EDITOR.

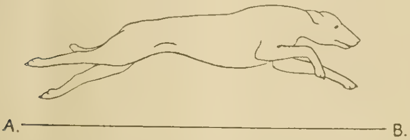
[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Gallop of the Horse and the Dog.

In a note in Nature of October 28 (p. 526) it is stated that Mr. Francis Ram, in a recent book, says I am in error (in an article lately published by me) in regard to the position of the legs and feet in a running dog.

I have not seen Mr. Ram's book, but I should be glad if you will print the enclosed outline figure of a running dog taken from a series of instantaneous photographs of a running dog by Mr. Edward Muybridge.

The horizontal line AB gives the actual level of the ground below the dog. The figure is one drawn for a book which I have in preparation, and I think has considerable value, since it serves to establish my suggestion that the Mycenæans (who were the originators of the pose of the galloping horse, which was never used by Greeks, Egyptians, Assyrians, Romans, or Europeans, but travelled, as Salomon Reinach has shown, across Tartary to China and Japan, and came from Japan to England at the end of the eighteenth century) did not *invent* the well-known conventional pose, but *observed* it in the dog, and very reasonably, but incorrectly, *applied* it to representations of the horse and other animals which do not really assume that pose. The pose in question satisfies the artist's judgment even when applied to the horse, because the outstretched position of the hind legs, with upturned hoofs and the forward-reaching position of the fore-legs, do *succeed* one another in the galloping horse so rapidly as to cause, not a continuity of the retinal impressions, but a continuity of the more slowly formed mental appreciations of the positions of the legs.



It is an important fact that the late Prof. Marey, of Paris, did not succeed in photographing the dog with all the feet "off" the ground and the legs in the position shown in Muybridge's photographs, and consequently archæologists have supposed that the Mycenæans imagined the pose as an artistic expression of rapid galloping. It seems to me, on the contrary, certain that they constantly saw and admired this pose in their hunting dogs.

E. Ray Lankester.

29 Thurloe Place, South Kensington, October 29.

The Refractivity of Radium Emanation.

We have read with special interest the communication from Lord Rayleigh in Nature, October 28 (p. 519), on the determination of the refractivity of gases available only in minute quantity, because we ourselves have been working towards the same end at intervals during the last two years. Our object in view was also the same, viz. the determination of the refractive index of radium emanation; not only for the intrinsic interest of a knowledge of the refractivity in question, but also because of the great probability of the emanation being one of the series of non-valent elements, and the determination would therefore enable us to extend the series of simple integers which has been found by one of us to connect together the refractivities of the other elements in the series.

The extremely minute quantity of emanation available—not more, after undergoing the ordeal of purification, than about one-tenth of a cubic millimetre measured at atmospheric pressure—made it quite clear that the refractometer to be employed must be on a minute scale, and the form which it seemed to us would probably lead to the most accurate results in the circumstances was one on the principle of a Fabry and Perot *étalon*, partly on account of the sharpness of the bands thus obtainable and partly because it is the *double* thickness which constitutes the path difference between successive interfering beams, and consequently the gas contained is utilised twice.

A capillary tube of glass (or fused silica) was sealed at one end, and a transverse hole was drilled passing through the extreme end of the bore. Two parallel faces perpendicular to the axis of the hole were then ground on the tube, and parallel plates of glass (or silica), silvered (or platinised) on the inside, were then cemented on the faces with Coate's cement. For this apparatus we had recourse, as usual, to the excellent workmanship of Messrs. Hilger. The result was a tiny interferometer vessel, 2·271 millimetres long and 0·71 mm. diameter, into which we could compress the emanation through the capillary tube by means of a mercury column in the usual way. When this interferometer was set up in the path of the green beam separated spectroscopically from the light given by a Bastian mercury lamp, and the light passing through was examined through an astronomical eye-piece—the lens system throughout being chosen so as to give best illumination—the interference bands which were obtained were all that could be desired, it being easily possible—when the silvering was of the best thickness—to measure micrometrically to the hundredth part of a band.

The method of a determination, in general outline, consisted in alternately increasing and decreasing the pressure of the contained gas from and back to a practically zero value and observing the number of interference bands which passed over the cross-wire of the micrometer. In order to determine the efficiency of the arrangement, observations were made for the refractivity of air, with the result that we think we are justified in claiming that an accuracy to within about 2 per cent. could be relied upon, so far as the optical part of the experiments is concerned.

The real difficulties begin, however, when we deal with the emanation itself. The rapid generation of impurities, originating in part in the action of the emanation upon the resinous cement employed for fixing the parallel plates, together with the lack of a knowledge of what these impurities are, made it impossible to calculate the index of the emanation from the experimental results, although it was perfectly easy to measure the refractivity of the mixture of gases existing at any time. The only datum known in regard to the composition of the mixture was the approximate percentage of emanation present, this being found by measuring the γ radiation from it. The direction in which the refractivity lies may, however, be inferred with probability from the following observations. Starting with emanation given off from a solution and containing a very large amount of impurity, this was purified, first, by explosion, drying, and absorption of CO_2, and afterwards by freezing in liquid air and pumping off the volatile impurities according to well-known methods. Testing the refractivity from time to time, its value—at first of the order of that of air—did not sensibly rise until the volume was about one cubic millimetre. Continued purification increased the refractivity, and the highest values obtained in our experiments were 0·000840 when the volume was 0·205 mm.^{3} (at atmospheric pressure) and 0·000916 when the volume was 0·128 mm.^{3} measured at atmospheric pressure. The quantity of emanation was approximately the same for both these measurements, and equalled the quantity in equilibrium with 0·178 gram of radium. Of course, if we could assume that the impurities were the same in kind on the two occasions it would be possible to estimate from these data the value for the pure substance, but the failure of this method on many occasions to give consistent results took away all belief in its applicability. For purposes of comparison we may state that the higher of the above values is about twenty-six times the value for helium, while the value for xenon—the highest for any known gaseous element—is twenty times, and for CO_2 thirteen times, the value of helium.

One source of difficulty so long as the available amount of emanation is so small is that the maximum pressure to which it can be raised in the apparatus is only a few (7 or 8) centimetres. The capillary correction thus becomes exceedingly important, and Sir W. Ramsay has given reasons for believing that the capillary behaviour of mercury is quite abnormal in the presence of emanation. Another serious difficulty with which we had to contend was that, under the action of the emanation, the silver (or platinum) through which the light had to pass gradually became opaque. The consequence was that the apparatus had each time to be dismounted after a couple of days, the faces re-polished, re-silvered, and re-installed before a new experiment could be begun. This source of inconvenience would, of course, not be present in apparatus similar to the Young-Arago method employed by Lord Rayleigh or in a Jamin refractometer (which we think is the more satisfactory of the two), but we do not think that it would be possible to obtain an equal optical efficiency with these arrangements.

The amount of success attending these experiments—small though it may seem to be—justifies us in hoping that if the amount of available emanation were increased a few times only an approximate value of the refractivity would be ascertainable. Even at the present time this might be effected by means of a collaboration amongst all those in the United Kingdom who possess large quantities of radium.

In conclusion, we desire to express our thanks to Sir W. Ramsay for generously supplying us with the emanation with which these experiments were made.

Alfred W. Porter.
Clive Cuthbertson.

Atmospheric Cloudy Condensation.

In Nature of October 21 Sir Oliver Lodge, writing on the recent magnetic storm, seems to think that during these storms the sun is emitting electric projectiles which cause the magnetic disturbance, and that these projectiles will, at the same time, affect the rainfall by the influx of "cosmic nuclei." From this, I presume, Sir Oliver means that the electrons passing through our atmosphere will produce ions in the air, and that these ions will become nuclei of condensation, and in this manner may increase temporarily and locally the rainfall. Now, so far as is at present known, it does not seem probable that these electrified nuclei play any part in cloudy condensation. That they can become centres of condensation is not doubted, but before they can act in that way the atmosphere has to become very highly supersaturated.

These ions, therefore, cannot play any part in the condensation unless all the dust in the air be first removed. The question thus becomes, Is there such a thing as dust-free air in our atmosphere? So far as I am aware, no such condition has ever been observed. I have returns of observations made in many parts of the world by different observers, as well as by myself. Some of these tests were made while crossing the Atlantic Ocean, others on the Pacific Ocean. Many were made in this country and in different countries on the Continent. Some were made at sea-level, others up to an elevation of 13,000 feet, but none of these records shows anything like dustless air. Mr. Rankin, in his Ben Nevis report, says "any number less than 100 particles per cubic centimetre is phenomenally small." Mr. E. D. Fridlander, at an elevation of more than 13,000 feet on the Bieshorn, found 157 particles per c.c. In many hundreds of observations made by myself on the Rigi Kulm (6000 feet) nothing quite so low as 200 per c.c. was ever observed. The reports of the observations made on the oceans show the dusty air to be everywhere, and there does not seem to be much chance of ever finding dustless air, at least so low as cloud-level, as the air with least dust is not found in the descending currents of anticyclones, but in the cyclonic areas, where the air is well washed by the rains. It may be further stated, in connection with this subject, that there is no reason for supposing that an increase in the number of nuclei would have any effect on the rainfall, as in nature only a few of the nuclei do all the condensation, while the others remain inactive.

This letter may seem longer than the subject warrants, but my reason for entering so fully into the subject is that the idea is now very generally accepted that ions do form the nuclei of cloudy condensation in our atmosphere. So stereotyped has this theory become that there is not a scientific book recently published in which this subject is treated which does not give this view. Now, so far as our knowledge at present goes, there is no support for this theory, and those who advocate it will require to show that there is ever dustless air at cloud-level. I have elsewhere shown that, even supposing there was dust-free air, clouds would not likely be formed, but the supersaturation would be relieved by the direct formation of rain, as the condensation in the highly supersaturated air would take place on only a few nuclei, which would grow very rapidly to rain-drops.

It is not here contended that the passage of the electrons through our atmosphere will have no effect on the rainfall, only that it has not been shown that there are ever the conditions necessary for the ions so formed to act as nuclei of cloudy condensation. That the electrons may act in some way in determining the coalescence of cloudy particles to form rain-drops seems possible, but, so far as I am aware, even this has not been demonstrated.

Ardenlea, Falkirk. John Aitken.

Magnetic Storms.

J'ai lu avec le plus grand intérêt dans le No. 2083 de ce périodique la note importante de M. le docteur Chree sur la dernière grande perturbation magnétique du 25 septembre, 1909.

Comme je fais depuis 1882, j'ai cherché de la mettre en relation avec le passage de la grande tache solaire australe qui a été observée, dessinée et relevée à l'observatoire de Catane par l'assistant M. L. Taffara tous les jours depuis l'apparition au bord est le 18 septembre jusqu' à la disparition au bord ouest le 29 septembre, excepté les jours 19 et 22, où l'observation a été empêchée par les nuages.

De nos observations il resulte que la tache doit être passée par le méridien central le 23 septembre, environ à 5h. soir, temps moyen de Greenwich.

Dans la relation de M. Chree n'est pas donné le temps du maximum de la perturbation, parceque les oscillations des appareils magnétiques de l'observatoire de Kew étaient souvent plus amples de ce que pouvaient être enregistrées. En considérant le commencement et la fin des oscillations plus amples, on a les temps 11h. 43m. et 8h. 30m. et la moyenne 4h. 7m.

Si l'on fait la différence avec le temps du passage de la grande tache, c'est à dire sept. 25, 4h.–sept. 23, 5h.= 1j. 23h.=47h., on a le retard de la perturbation magnétique sur le temps du passage de la tache à la moindre distance du centre du disque solaire, c'est à dire à la moindre distance de la droite qui unit le centre du soleil à la terre.

Ce retard est très peu différent de celui de 45½h. que j'ai trouvé en moyenne pour 8 coïncidences de passages de grandes taches avec le maximum de fortes perturbations magnétiques du premier semestre 1892; ce retard aussi n'est pas trop différent de celui de 42½h. que j'ai trouvé entre le temps moyen du commencement et de la fin de 19 grandes perturbations magnétiques et le temps des passages de grandes taches, ou de grands groupes de taches, d'après les relèvements de M. Maunder de l'Observatoire de Greenwich.

Il serait donc confirmé aussi pour cette grande perturbation magnétique un temps de 40 à 50 heures pour la propagation du soleil à la terre de l'influence ou action solaire sur le magnétisme terrestre; ce qui donnerait une vitesse de 900 à 1000 km. par seconde; c'est à dire une action plus que 300 fois moindre de celle de la lumière et des actions électromagnétiques. Mais cette vitesse pourrait bien être celle des particules émises par le soleil, selon les idées de M. Arrhenius.

Ainsi l'hypotèse corpusculaire de l'influence solaire acquiert toujours une plus grande probabilité.

L'assistant M. le Dr. Horn a fait à l'Observatoire de Catane presque à tous les jours du passage de la grande tache les photographies au spectrohéliographe, mais on n'a pas obtenu autour de la tache des très-grandes masses faculaires. A. Riccò.

Catania, October 10.

High Pressure Spark Gap in an Inert Gas.

FOR some years I have employed a high-pressure spark-gap, such as that described by me in the *Phil. Mag.* for August, 1902, in connection with a Tesla inductive system, and I have experienced considerable trouble arising from the erosion of the spark balls and their supports. They soon become coated with an oxide of the metal employed, and the sparking becomes unsteady. As a cure for this evil, which contributed much to the formation of a bad type of spark, the employment of some inert gas suggested itself to me; and of such gases Mr. C. C. F. Monckton proposed the use of nitrogen, and this gas I now use instead of air. I find that after the continuous use of nitrogen in the spark-gap the balls are but little affected, while the spark through a gas pressure of 50 lb. per square inch is compact and constant in shape, and the yield of the induction apparatus is greatly enhanced. The spark-gap globe is filled to the required pressure from the gas cylinder through a reducing valve, and when it is shut off the pressure is maintained for ten or twelve days nearly up to the initial one.

The nitrogen, which was supplied by the British Oxygen Co., compressed in a steel cylinder, turned out to be very nearly pure; it is separated from liquefied air, and is certainly more pure than hydrogen as supplied in cylinders, and gives better results. The spheres are made of thick white glass, and are tested to about four times the load they are worked under. The spark ball is advanced by means of a fine screw forty-eight threads to the inch, cut on ¼-inch rod, working in a boss which forms a part of the gun-metal cap with which the glass globe is closed. If the screw is carefully fitted by Whitworth screwing apparatus, no gland or stuffing-box is required. The screw is slightly lubricated with a mixture of equal parts of pure india-rubber and vaseline. The length of the spark is measured by means of a divided head attached to the screw.

It might be supposed that a long spark in air at normal pressure would have the same effect as a spark shortened by gas pressure; but experimental evidence shows that the thick, steady, well-formed spark made under pressure gives far the most trustworthy results. Sparks made in air at normal pressure often do not strike from the nearest surfaces, but strike along an arched path, this effect reducing the discharge and rendering it variable in its intensity; but when the high-presseure nitrogen spark-gap is employed, the discharge from the Tesla apparatus is steady and unvarying during periods of time such as forty or sixty minutes.

The Small Motion at the Nodes of a Vibrating String.

IT is generally recognised that the nodes of a string which is maintained permanently in oscillation in two or more loops cannot be points of absolute rest, as the energy requisite for the maintenance of the vibrations is transmitted through these points. I have not, however, seen anywhere a discussion or experimental demonstration of some peculiar properties of this small motion. A brief note may therefore be of interest.

In the first place, the small motion at the node is in a phase which is different from that of the rest of the string. The exact difference of phase is shown by a dynamical investigation to be a quarter of an oscillation. The motion is of very small amplitude, and it might therefore be thought a difficult matter to verify this experimentally. I have, however, devised some convenient arrangements with which this can be effected. I shall here mention only one method: this was to compound the oscillation at every point on the string with another perpendicular to it of half the frequency, and to observe the compound oscillation at the nodes and elsewhere.

Such a compound oscillation can easily be maintained permanently by having the string attached to the prong of an electrically maintained tuning-fork, so that it lies in a plane perpendicular to the prongs, but in a direction inclined to the line of their vibration. When the load on the string is slightly greater than that necessary for the most vigorous maintenance, points on the string describe parabolic arcs with concavities in opposite directions in alternate loops, the whole forming a beautiful and interesting type of stationary vibration. This is not, however, the stage convenient for observing the small motion at the nodes. When the tension of the string is relaxed, so as to make its vibration stronger, points on the string, *i.e.* except the node, describe 8 curves. The curve described by the node is neither a straight line nor an 8 curve, but is a very flat parabola. From this, the phase-relation between the small motion at the nodes and the large motion elsewhere is obvious.

If the node has a small motion, then, strictly speaking, there is no node at all. There should, however, be points at which the positions of the string in opposite phases might be supposed to intersect. One might suppose that these points, or "fictitious nodes," should execute a very small, almost microscopic, movement. As a matter of fact, these "fictitious nodes" oscillate parallel to the string through a range equal to the whole length of a loop. This somewhat striking effect may be observed without difficulty by illuminating the string with periodic illumination of twice the frequency of the oscillation.

Post-Box 59 Rangoon. C. V. RAMAN.

An Instance of Prolonged Pupation.

THE following facts in connection with a specimen of the privet hawk-moth may possibly be of interest to some of your readers.

The caterpillar, which was reared from the egg at Tunbridge Wells, pupated between August 7 and 9, 1906, and the pupa was sent out to me by post. The moth did not emerge until October 16, 1908, having been more than two years in the pupal state. Being the only specimen I have, I cannot say whether it shows any variations; but it is not stunted, measuring just over 4 inches across the expanded wings.

Sydney, N.S.W.

A SCIENTIFIC MISSION IN ETHIOPIA.[1]

ABYSSINIA—and even in a more general way the whole Empire of Ethiopia—though it was the first portion of tropical Africa to come within what one might term the scientific cognisance of the civilised world, the world of Mediterranean Europe and Western Asia, remains, nevertheless, to this day the least understood and one of the most imperfectly explored parts of Africa. In all probability, more is known about the fauna, the flora, the human races, and languages of even the most recently revealed recesses of the Congo Basin, of the Central Sudan, the Liberian hinterland, and the south-western part of the Niger Basin (to mention some of the least-known parts of tropical Africa) than is recorded of the dominions of the Emperor Menelik.

This ignorance of Ethiopia (from the point of view of modern science) is, of course, proportionately estimated in relation to the extraordinarily important position all this region occupies in the study of Africa, in the solution of African enigmas. It is an area of about 200,000 square miles, containing exceptionally high mountains, the tops of which, but for the increasing aridity of North-East Africa, should be even more covered with glaciers than is the case with Ruwenzori, under the Equator, for the Ruwenzori range only exceeds in altitude by a few hundred feet the estimates of the highest points of northern and south-western Abyssinia. In Abyssinia alone, of all parts of tropical or Trans-Saharan Africa, may distinct evidences be found of the existence (on the high mountains and even in the plains) of a Eurasian fauna and flora—wild swine of the genus Sus, wild goats, wild dogs (*Canis simiensis*), and a few other beasts and a number of birds, trees, and plants, which in their affinities belong more truly to the Palæarctic and subtropical regions of Europe and Asia than to true Africa. There are also indigenous non-Negro races, like the Gala, which, by skull formation, by their use of the plough (absolutely unknown elsewhere in Negro Africa), by their languages, and many other points, are Asiatic rather than African.

---

[1] "Mission en Éthiopie (1901–3)." By Jean Duchesne-Fournet and others. Tome i., pp. xviii+440; Tome ii., pp. xv+388, and atlas. (Paris: Masson et Cie., 1909.)

Yet there are indications that Abyssinia, like Somaliland, Egypt, Mauretania, has been inhabited by man from a most remote period. Abyssinia may have been the first great focus of *Homo sapiens* on the African continent, to the south of the Sahara Desert; the region from which radiated Pygmies, Bushmen, Nilotic Negroes, Forest Negroes, and Bantu; Hamite, Egyptian, and the widespread negroid types typified by the modern Fula, Hima, Nyam-nyam, and Tibbu. Here took refuge an ancient offshoot of the Jewish people; here first of all with the armies of Ptolemy, was carried Greek civilisation into tropical Africa; hither came Persians after they had conquered southern Arabia; even more anciently than Jew or Persian a branch of the Semitic peoples was implanted in Abyssinia, which has left behind to this day at least two distinct language-groups of the Semitic family—Amharic and Harrari—in addition to the much later Arabic.

Here we are in one of the few portions of tropical Africa known to the Romans and to the civilised kingdoms of India before the time of Christ. (*Habshi*—derived from *Habesh*, an old Semitic name for Abyssinia—is even at the present day the common word for *negro* throughout Hindustan, and is also equivalent to "magician," because in the ancient lore of India, Abyssinians were identified with all the unholiest forms of magic. They are the "black magicians" of the "Arabian Nights'" stories. When the present writer first imported Sikh soldiers into Central Africa to fight the Arab slave traders, brave as they were in the presence of Arabs, they were at first frightened of the friendly negroes. "He is a Habshi, and will turn me into a rabbit," said one stalwart Sikh soldier to me when I asked him to travel alone through the bush with a negro guide.)

The Portuguese soldiers and missionaries first revealed some marvels of Abyssinia and Ethiopia to the modern European world of the later Renaissance. The Portuguese also, by splendid feats of arms, saved Christian Abyssinia from being conquered and effaced by a great army of Arabised Somalis under Muhammad Granye. Then came an interval of Abyssinian distrust of the greedy white man, and the attempts of Louis XIV. to supplant the Portuguese and frenchify Abyssinia in the seventeenth and eighteenth centuries led finally to great disasters, though it increased the acquaintance of the European world with these profoundly interesting countries. After that came the awakening of British interest through the travels of Bruce and Salt. The last named (Henry Salt) added considerably to our knowledge of the peculiar fauna of these countries.

During the first half of the nineteenth century, French interest in Abyssinia had a notable revival, and to the brothers D'Abbadie (of French-Irish origin) we owe much of our meagre knowledge of the Hamitic and negroid dialects of western Abyssinia and south-west Ethiopia. After this came British big-game hunters, consuls, and, finally, an army of British and Indian soldiers. Mr. W. T. Blandford, amongst other notabilities in zoology and geography, accompanied this expedition, and again revealed further remarkable features in the mammalian fauna of this peculiar part of Africa.

We have learnt a little more since from British and Italian missionaries and explorers (notably, as to fauna, from Major Powell Cotton), but more still from French expeditions, important among which have been those of the late Baron Carlos d'Erlanger and Baron Maurice de Rothschild.

One of the most remarkable French expeditions (not forgetting the work of Borelli some sixteen years ago) lately undertaken for the examination of Abyssinia and Ethiopia, is that which is the motive and the source of the present notice.

In a rather too intimate and emotional preface to this work, addressed to the father of Jean Duchesne-Fournet, we are told that this young and brilliant French explorer died in 1904, after his return from Abyssinia. In the course of his journeys he had reached the Wallaga country during the rainy season, and had suffered to a terrible extent from fevers, the sequelæ of which caused his death after his return to France. He was, in fact, a martyr to science, for the Wallaga country is a very little known part of East-Central Africa, lying to the south of the Blue Nile and of the Didessa River, and at no great distance from the frontier of the Egyptian Sudan.

The special object of Duchesne-Fournet's exploration of Wallaga was its reputation, not only as a possible source of future wealth in gold, but as a region from which gold was obtained in the distant past for the ancient Egyptians. Apparently a concession had been granted in that region to a French syndicate, and an active exploration was being carried on by a French engineer, Monsieur Comboul (who afterwards died). The Wallaga country has a mean elevation (averaging the French and Italian calculations) of about 6000 feet. It seems to have been visited by Jean Duchesne-Fournet alone (with an Algerian escort), or, at least, without any one of the French men of science on his staff, consequently, from the point of view of science, his incursion into this south-westernmost portion of the Emperor Menelik's dominions had little results of importance. He describes this country as "ravissant surtout avec sa belle verdure." It has a certain amount of woodland, rare elsewhere in the Abyssinian Empire. The rainfall is extremely heavy, and the country to a great extent lies within the basin of the River Didessa, an important southern affluent of the Blue Nile. It is covered with a luxuriant vegetation, and, where there is any agriculture (the land is inhabited sparsely by Galas and Walamo negroids), wheat, barley, maize, sorghum, beans, peas, potatoes, coffee, limes, bananas, and cotton are cultivated. The engineer Comboul seems to have found deposits of lignite, the importance of which was appreciated by the Emperor Menelik. But although in beauty this region was a paradise, and in products one of the richest parts in Africa, the climate seems to have been singularly unhealthy—constant fevers, not to be explained easily under the mosquito theory of infection, and terrible rheumatisms made its exploration during the rainy season almost a torture. Some of the great mountains (the summits of which would seem to reach here and there to 10,000 feet) contained immense caves, the exploration of which might yield important results in palæontology and palæanthropology.

The premature death of the leader of this expedition (the other members of which were Lieutenant Collat, Sergeant-Major Fontenaud, Louis Lahure—who afterwards greatly distinguished himself in explorations between the Benue and Lake Chad—H. Arsandaux, Dr. Goffin, and Dr. Moreau) to some extent spoilt the realisation of the full scientific results; as it is, the material collected and presented in the two volumes and the atlas of this book, give us, first of all, a most important *aperçu géologique* of the Danakil country, French Somaliland, and southern Abyssinia as far as Addis-Abeba, and a petrographical study of the same regions, with analyses of the rocks and minerals collected, and many photographs to show the types of landscape. These photographs are most conscientious, but the country presented to our eyes between Addis-Abeba and the Gulf of Aden is certainly one of the least alluring of all Africa. The Sahara Desert is much more attractive from the painter's point of view.

Some beetles were collected and are described. There is a most important article (taking up a considerable proportion of the second volume) on the anthropology and ethnography of southern Abyssinia, by Dr. R. Verneau, of the Paris Museum of Ethnography. This is accompanied by admirable photographs of skulls, of clothing and adornments, of musical instruments, pottery, jewellery, and horse harness; but the photographs taken by the expedition of living human types are, with one or two exceptions, not good or trustworthy, since they have been too much touched up in order to make them presentable pictures, or else they are very minute. The author of this section (Verneau) would seem to have arrived at the following general conclusions:—That in the portions of Abyssinia and northern Ethiopia in which the Duchesne-Fournet expedition collected skulls and took careful measurements of the living body, there were, besides the pure-blooded Negro, three distinct human types:—(1) The *Amhara* or *Abyssinian* (with which might also be grouped the *Gala*; (2) the *nigritised Abyssinian* (simply the result of ancient and modern intermixture between the Hamite—Abyssinian, Gala—and the Negro); and (3) a most interesting form, the *Berber* (this is a short title for the descriptive term given by Dr. Verneau, who calls it, "Type Abyssin clair, à cheveux lisses ou ondulés," and elsewhere, "Berbère"). This "third ethnic element" he describes as "very different from those which I have already set apart." It is one which has made its influence felt in Abyssinia, but, like the Negro element, it has crossed with the Hamite or Ethiopian (type No. 1), and as the result of this mixture its characters have become sensibly attenuated. "Nevertheless, one may affirm that this type No. 3 is of a fair complexion, slightly *cuivré*, and is further notable because it has evidently lightened the complexion of the skin in 13·5 per cent. (approximately) of the actual population." "Type No. 3," he goes on to say, "has blue eyes, or must have had blue eyes originally; for one could scarcely derive the blue, grey, or green iris (which is that we have noted in the proportion of 11·7 per hundred amongst modern Abyssinians) from the Ethiopian or the Negro. It is also type No. 3 which has certainly introduced the smooth or very slightly undulating hair, which has been found in 13·2 per cent. of the individuals under examination. On the other hand, this light-skinned race has not introduced tall stature amongst the people, but rather lessened the stature of the Abyssinians as compared with that of the Hamite and negroid races farther south."

In this race, Dr. Verneau apparently sees a marked resemblance to the Kabail of Abyssinia. One of the skulls depicted seems to display affinities with the Cro-magnon race of Western Europe.

There is a most comprehensive bibliography of Ethiopia in this work under review, a work which whets one's appetite for a complete examination of Abyssinia.

H. H. JOHNSTON.

THE SYSTEMATIC MOTIONS OF THE STARS.[1]

A SYSTEMATIC character in the proper motions of stars was discovered by Herschel, and accounted for by the motion of the solar system in space. Herschel's conclusions were for a time disputed by Bessel, but were confirmed by Argelander, and have since been generally accepted. In the last quarter of a century many determinations of the direction of the solar motion have been made, but the results have not shown that accordance which might have been anticipated. Particularly noticeable are the different results obtained from the proper motions determined by Auwers of the stars observed by Bradley in 1750, and re-observed about 1860, according to the method employed. Applied to these stars, the mathematical methods of attacking the problem developed by Airy and Argelander place the solar apex, or point to which the sun is moving, in declination +35° or thereabouts, while Bessel's method places it at −5°. In 1895, Dr. Kobold directed attention to these discrepancies, which seem to point to an error in the fundamental hypothesis underlying these methods of determining the direction of the solar motion. These methods are based on the assumption that the "peculiar" motions of the stars are haphazard, and have no preference for any particular direction or directions in space.

As an outcome of prolonged study of the subject, Prof. Kapteyn announced, in 1905, at the meeting of the British Association in South Africa, that this hypothesis was untenable. He used the well-determined proper motions of 2400 stars extending from the pole to 30° south of the equator given in Auwers-Bradley. Dividing this area of the sky into twenty-eight regions, he determined the directions of the apparent proper motions of the stars in each region, and found that they showed a preference for *two* special directions and not for one only. When these favoured directions for the twenty-eight areas were plotted on a sphere, they were seen to converge to two points. Convergence to a point on the sphere indicates that the apparent linear motions of the stars are parallel, just as the radiant point of a meteor stream indicates the direction in which the meteors are all apparently travelling. Relatively to the sun, therefore, the stars are moving in two streams, inclined at a considerable angle to one another; these motions are apparent only, and, when the solar motion is subtracted, are resolvable into two streams moving in diametrically opposite directions, relatively to the centre of gravity of the stars. Kapteyn showed that the stars were equally distributed among the two streams, and that their relative motion was in a line in the plane of the Milky Way, directed towards the star ξ Orionis (R.A. 91°, decl. +13°) and the opposite direction. The apparent motions of the stars are thus resolvable into a combination of (1) a haphazard motion, (2) the reversed solar motion relative to the centre of gravity of the stars, and (3) the stream movement in the direction of ξ Orionis and the opposite direction. It was pointed out by Kapteyn that the determinations of the solar motion made by Airy's method, the one most generally adopted by astronomers on account of its simplicity and convenience, were not much in error, in spite of the systematic character of the motion of the stars in these two streams. For the equations which result from Airy's method agree closely with those of a valuable method of determining the solar motion due to Bravais, which does not assume the haphazard character of the peculiar motions of the stars. But an entirely new fact in stellar astronomy has been elicited in the discovery of the systematic movements towards and away from ξ Orionis.

(5) F. W. Dyson, Proceedings of the Royal Society of Edinburgh, 1908, vol. xxviii., part i., p. 231; 1909, vol. xxix., part iv., p. 376.

Mr. Eddington introduced a precise mathematical definition in place of the somewhat nebulous phrase star-stream. A "drift of stars" is defined as a group of stars the velocities of which relative to some system of axes are quite haphazard. The velocity of the "drift" is the velocity of the system of axes, while the "peculiar" velocity of a star is its haphazard velocity relative to the system of axes. Haphazard is defined as a distribution of velocities, according to Maxwell's law for the molecules of a gas. Formulæ are then developed to give the distribution of the directions of proper motions in any small area of the sky which would arise from the projection on the face of the sky of a star drift with a given mean peculiar velocity and a "drift" velocity given in magnitude and direction. Mr. Eddington applied his method to the consideration of the proper motions in Groombridge's catalogue, recently determined at Greenwich by Messrs. Dyson and Thackeray. The catalogue contains about 4500 stars within 52° of the North Pole, a large proportion being between magnitudes 7 and 9. Comparing the actual distribution with a theoretical one, based on the assumption that the stars form two drifts, he found close accordance. The stars were equally divided between two "drifts" the apparent directions of which were in good agreement with Kapteyn's results. The two streams did not show any distinctive features, each contained bright and faint stars, and stars of all types of spectrum, and, further, the mean distances from the sun of the stars contained in the two "drifts" were the same. Additional confirmation was obtained from 1200 stars within 10° of the North Pole, the proper motions of which had been determined by comparison of the Greenwich positions in 1900 with those found by Carrington in 1855. In a later paper, and by a somewhat different method, about 2000 fairly bright zodiacal stars were also examined.

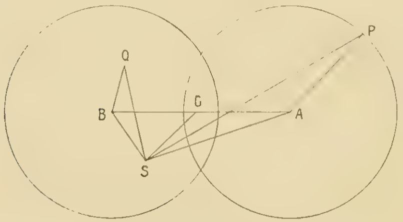

FIG. 1.—Velocity diagram according to Eddington's hypothesis.

According to Mr. Eddington's determination, the velocity of one stream relatively to the sun may be represented by SA, and that of the other by SB, while the haphazard velocities of the stars composing the streams are equally in all directions from the centres A and B, and their mean values are represented by the radii of the two spheres. The solar velocity relative to the centre of gravity of all the stars is represented by SG, and the rates at which the streams are separating by AB. If SP denote the velocity of one star relatively to the sun, this may be analysed into SA, the "drift" velocity, and AP, the "peculiar" velocity (which in this instance has its mean value); the drift velocity SA may be analysed into SG, the solar motion, and GA, the velocity of the stream. Similarly, SQ, the velocity of another star, may be resolved into a component of the second stream, the peculiar velocity of which is BQ, or only half the mean value.

Prof. Schwarzschild assumes that the "peculiar" motions of the stars do not obey Maxwell's law, but a slightly modified law in which the resolved parts of the velocities in one direction are all increased in a definite proportion, thus giving a spheroidal instead of a spherical distribution. When combined with the solar motion, this distribution of "peculiar" velocities gives two favoured directions for the proper motions of the stars included in any small area of the sky, and has the advantage of representing the stars as a single instead of a dual system. Applied to the Greenwich-Groombridge proper motions, the assumption shows a very satisfactory accordance with facts. According to Prof. Schwarzschild, the observed proper motions of these stars would be produced by a velocity of the solar system SG and "peculiar" velocities of the stars the mean values of which in different directions are radii of the prolate spheroid ABA′B′. Thus the velocity SQ of a star is resolvable into SG, the solar motion, and GQ, the "peculiar" velocity. In this instance the "peculiar" velocity is one-half the mean "peculiar" velocity belonging to the direction GQ. In his second paper Prof. Schwarzschild develops his theory with great mathematical elegance so as to make it applicable to cases where the number of stars per unit area is small. In this form it is applied by Mr. Beljawsky to the stars of large proper motion in Prof. Porter's catalogues, although its application is not free from objection, as these stars were selected on account of their large proper motion, while the method is strictly only applicable to unselected proper motions.

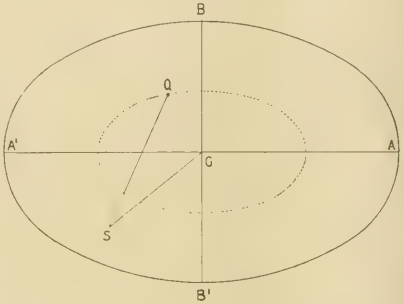

FIG. 2.—Velocity diagram according to Schwarzschild's hypothesis.

Prof. Dyson collected all the proper motions greater than 20″ a century from various sources, and by a simple graphical method determined the favoured directions of motion. Partly owing to the small effect of accidental error of observation on the direction of the proper motion of these stars, and partly because only large proper motions were considered, the two apparent star streams were shown with great clearness. In the large majority of cases it was possible to assign individual stars to one or other of the two streams, and thus a verification was obtained of the result that the two streams showed no difference as regards the magnitude or type of spectrum of the stars in them. Of 1800 stars examined, 1100 belonged to the first stream, 600 to the second, and the remaining 100, which could not be assigned to either, showed no motion of a systematic character. The large proportion of stars belonging to the first stream arises from the mode of selection according to the magnitude of proper motion. Kapteyn's and Eddington's result, that when stars are taken without selection they are equally divided between the two streams, is used to determine the ratio of the stream velocities. When this is determined the apparent movement in two streams, as seen from the earth, is replaced by the solar motion and two streams moving in opposite directions relative to their centre of gravity.

There is at first sight considerable difference between Kapteyn's description (followed by Eddington and Dyson) of the systematic movements of the stars, and that of Schwarzschild. The dual character of Kapteyn's system should not be unduly emphasised. Division of the stars into two groups was incidental to the analysis employed, but the essential result is the increase of the peculiar velocities of stars towards one special direction and its opposite. It is this same feature, and not the spheroidal character of the distribution, which is the essential of Schwarzschild's representation. The results obtained by the two methods agree very closely. Defining the "apex" as the direction of the sun's motion relative to the centre of gravity of the stars. and the "vertex" as the direction of motion of one stream relatively to the other (Kapteyn) or the major axis of Schwarzschild's spheroid, the accordance of the different results is shown in the following table:—

	Apex R.A. Dec.	Vertex R.A. Dec.
Kapteyn—Bradley stars	— ...	91 + 13
Eddington—Groombridge stars ...	266 + 31 ...	95 + 3
Schwarzschild—Groombridge stars ...	266 + 33 ...	93 + 6
Dyson—Stars of large proper motion.	281 + 42 ...	88 + 24
Beljawsky—Porter's stars	281 + 36 ...	86 + 24
Eddington—Zodiacal stars	— ...	109 + 6

It may be noticed that the Groombridge stars gave almost identical results by the methods of Eddington and Schwarzschild, and that Beljawsky and Dyson, whose material was very similar, obtained results in close accord.

Although attention may be directed to Kapteyn's observation that the vertex lies in the plane of the Milky Way, it is too soon to offer any explanation of these remarkable movements of the stars. To have disentangled them from the irregular proper motions of the stars is itself a very important step. By clearing up the difficulty in the anomalous results previously found for the direction of the solar motion, and by the discovery of systematic movements in which all the stars share, Prof. Kapteyn has made the most important contribution to this branch of astronomy since the time of Herschel.

F. W. DYSON.

THE SEA OF ARAL.

RECENT explorations in Central Asia, and the evidence accumulating from many quarters of general desiccation of that area within historic times, give special interest and value to anything in the shape of observations of even approximate precision which point towards an opposite conclusion, or to a conclusion that variations in the amount of precipitation, where they occur, are more or less local and constitute merely a phase which, although it may be of relatively long period, does not represent continuous progressive change. The work carried on by L. S. Berg in the Sea of Aral between the years 1900–1906 form an important contribution to the subject of limnology generally, and more particularly to this question of desiccation. The original report on these investigations (Berg, "The Sea of Aral," St. Petersburg, 1908) is published in Russian, but students unfamiliar with that tongue may acquaint themselves with the present state of knowledge concerning the whole region by means of an article by Prof. Woeikow, published in the April number of *Petermann's Mitteilungen*. Prof. Woeikow deals primarily with Berg's observations, and his maps are reproduced, but he uses information derived from other sources, for purposes of comparison.

The Sea of Aral is situated at an elevation of 50 metres above mean sea level, and its area of 63,270 square kilometres places it fourth in size amongst the inland lakes of the world. The mean depth is 16 metres, and the maximum 68 metres, depths exceeding 30 metres occurring only in one small depression in the west and two still smaller ones in the north of the basin. The volume of water is computed to be 1012 cubic kilometres, only slightly greater than that of Lake Ladoga, which has about one-quarter of the superficial area, and about one-tenth of Lake Baikal, which is little more than half the size. The supply of water comes wholly from the two rivers Amu and Syr, which together deliver, on the average, some 1500 cubic metres per second. Most of the water is derived from the melting of mountain snows, the months of maximum flow being June, July, and August. Berg gives the mean salinity as 10·75 *pro mille:* compared with analyses made during the 'seventies of last century, which yielded an average of over 12 *pro mille,* this shows a marked freshening, due, as appears, to an increased volume of water.

The survey of the Sea of Aral by Admiral Butakow in the late 'forties formed the first foundation of accurate knowledge, and there is evidence to show that at the time of that survey the level of the water was relatively high. Few precise measurements were made for a long time afterwards, but it seems certain that after the 'forties a period of falling level began, and continued for some thirty to thirty-five years. Borczow reported diminishing area in 1857. The period 1859 to 1874 is blank, or nearly so. Sewertzow, Subow, and Kaulbars (1873–4) found great shrinkage on comparison with Butakow's survey, and further comparison with the records of Meyendorff and Ewersman (1820) seemed to justify the conclusion that a general desiccation of this part of Central Asia was taking place continuously. K. Schulz, surveying in the north-eastern end of the sea in 1880, found still further shrinkage since 1874.

From 1880 to 1899, when Berg first visited the region, another blank occurs; but in 1899 Berg found a rise of level in full progress, the height already attained exceeding not only that of 1874 and 1880, but that of Butakow's records in the 'forties. Islands, for example, which appeared in Butakow's map, and which had become peninsulas in the 'seventies and 'eighties, were submerged. Working from the levels of Tillo at Karatmak, Berg estimated a height of 1·21 metres in 1901 above that in 1874. Glukhowskoy found a fall of 71 centimetres between 1874 and 1880, giving a rise from 1880 to 1901 of about 2 metres, or 9 centimetres a year. The rise has continued, and Berg now gives it as 2·75 metres in 1903, and 3 metres in 1908. The depth of the lake being mostly shallow, this rise corresponds to a very considerable increase in area; the increment in volume of water between 1880 and 1908 is estimated at 20 per cent.

Other lakes to the north, north-east, and east of Aral show a similar rise during the last fifteen or twenty years. Lake Balkash has been rising since 1890; Lake Aschikul, in the Tschu depression, which was dry in 1888, was full in 1900, and there is a marked rise in many lakes in the Kirghiz Steppe, along the line of the West Siberian railway, and elsewhere.

The observations of rainfall taken at Barnaul on the upper Ob since 1838 are of great significance in this connection. The annual amount diminished from 1838 till 1868, then increased rapidly till 1895, and it has remained high, with small variations, since that year, the highest five year average (to end of 1906) being 1902–6.

The evidence goes then to show that the supposed continuous drying up of Central Asia has no existence in fact, but that variations occur which may or may not be periodic. If they are recurrent, the period must extend over at least sixty years, and its precise length cannot be determined before the end of the twentieth century, at the earliest.

Prof. Woeikow adds an interesting section on the history of the Sea of Aral, which has, naturally, important bearings on the question of secular variations of climate. A rise of the river Amu of only 4 metres above the level of 1901 would cause an overflow of part of its waters by the Usboï to the Caspian, one effect of which would be that the sea of Aral would become a fresh-water lake. Historical evidence (see Barthold, "Scientific Results of the Aral Expedition," 1902; and "Historical Geography of Iran," 1903: Berthold, by the way, is of opinion that the climate of Iran and Turan, so far as can be gathered from historical evidence, has remained practically unchanged for 2400 years) goes to show that from the thirteenth to the end of the sixteenth centuries this overflow actually occurred; and it would seem that this was a period of comparatively high rainfall in eastern Europe and western Asia.

A final section of Prof. Woeikow's paper deals with the thermal relations of water and air over the Sea of Aral. Space forbids a summary of the extremely interesting results obtained from Berg's observations, which appeal, perhaps, more to the specialist.

The definite conclusions set forth by so high an authority as Prof. Woeikow are of profound significance. The variations in the breadth of the grass belts between forest and hot desert, whether "savana" or "steppe," afford some of the most complex problems awaiting the geographer; the variation is probably greater the greater the total width of the belt, and the area in which the rainfall oscillates above or below a *minimum* point determining the possibility of human settlement of one kind or another is probably also greater. If it can be established that there is in effect no real evidence to show that in Central Asia a continuous diminution of rainfall is going on, but that a period of 30 or 40 years, or even of 300 years, of relatively small rainfall has passed its minimum, and that a similar period of greater fall has begun, then it follows that the historical problem of the depopulation of many of those regions, a problem of which the question of water supply can form only one element, becomes greatly modified. A thirty years' drought is no doubt sufficient to depopulate any district which has a low rainfall at the best of times, but increased rainfall does not necessarily mean immediate repopulation; and it does not follow that a region which has been deserted by its population at one time, through drought or other cause, has remained uninhabitable ever since. Again, it may be that large areas which for fifty years or more have been regarded as beyond hope will before long yield to modern methods of development and be added for a generation to come to the wheat producing, or at least the "ranching" regions of the world.

It is well that a belief which has often, in the absence of direct evidence, been used to bolster up the conclusion that rainfall was also diminishing a long way from Central Asia (the writer has heard it seriously used to support the contention that diminished yield of wells sunk in the chalk of south-eastern England was due to secular change of climate) should be definitely disposed of irrespective of its irrelevance. Assuming that no case of constant progressive diminution of rainfall in any part of the world has been established, and that none is now likely to be established, the problem seems to be to ascertain the nature and duration of these variations extending over long intervals of time. Are they periodic? if so, what is the length of period? What is the current phase at different parts of the earth's surface, and to what is the difference due? Central Asia has apparently just passed a *minimum* phase—has Central Africa just passed a maximum? Apparently fifty years of observation will be required to settle these questions.

H. N. D.

NOTES.

SIR JOSEPH LARMOR, Prof. Felix Klein, and Prof. H. Poincaré have been elected honorary members of the Calcutta Mathematical Society.

THE new rooms of the Royal Society of Edinburgh will be inaugurated on Monday next, November 8, when Sir William Turner, K.C.B., F.R.S., president of the society, will deliver an address, and a reception will be held.

PROF. K. SCHWARZSCHILD, director of the Göttingen Observatory, has been appointed to the directorship of the Royal Astrophysical Institute of Potsdam, rendered vacant by the death of Prof. Vogel. His position at Göttingen is to be filled by Dr. J. Hartmann, hitherto an assistant at the Potsdam institution.

THE first fellowship established under the will of the late Dr. Sorby, F.R.S., of Sheffield, as reported in our issue of July 8 (vol. lxxxi., p. 42), has been awarded by the joint committee nominated by the Royal Society and the University of Sheffield to Dr. Jocelyn F. Thorpe, F.R.S., who will engage upon a research on the chemistry of the imino-compounds.

A REUTER message from New York states that Mr. J. D. Rockefeller has made a donation of 200,000*l.* in support of a commission of eminent medical men to investigate the hook-worm disease, which is prevalent in the rural districts of the southern States.

A MEETING to inaugurate the new observatory and meteorological station of the Hampstead Scientific Society will be held on Saturday, November 6, at 3.30 p.m., at Heath Mount School, Heath Street, Hampstead. Mr. P. E. Vizard will take the chair, and the speakers will be Dr. F. Womack and Dr. H. R. Mill.

THE eighty-fourth Christmas course of juvenile lectures, founded at the Royal Institution in 1826 by Michael Faraday, will be delivered this year by Mr. W. Duddell, F.R.S., his subject being "Modern Electricity." The course, which will be experimentally illustrated, will commence on Tuesday, December 28, and will be continued on December 30, 1909, January 1, 4, 6, and 8, 1910.

At the opening meeting of the Institution of Electrical Engineers on November 11, a marble bust, by Hamo Thornycroft, of the late Dr. John Hopkinson, F.R.S., who was president in 1890 and in 1896, will be presented to the institution by Prof. Bertram Hopkinson on behalf of his mother, Mrs. John Hopkinson.

A departmental committee has been appointed by the Home Secretary to inquire into the working of the existing special rules for the use of electricity in mines, and to consider whether any, and, if so, what, amendments are required. The members of the committee are:—Mr. R. A. S. Redmayne (chairman), Mr. C. H. Merz, and Mr. R. Nelson. Correspondence may be addressed to Mr. Nelson at the Home Office.

Preliminary particulars have been sent to us of the United Provinces Agricultural and Industrial Exhibition which is to be held in Allahabad in December, 1910. An agricultural court will form one of the main features of the exhibition, and will be arranged on a scale more extensive than anything previously attempted in India. The Agricultural Department of the United Provinces has assumed responsibility for the agricultural court, and inquiries regarding it should be directed to the Deputy Director of Agriculture, Cawnpore. It is hoped that this court will contain an economic collection of agricultural exhibits of interest, not only to the producer, but also to the consumer and to the manufacturer of finished articles from raw products.

Science in the daily Press usually consists of snippets of sensational information which if true is not new, and if new is not true. Any attempt to represent the true position of scientific work and thought, the progress of research, and the best aims of higher education for the enlightenment of the general public is worthy of encouragement. We are glad to see, therefore, that the *Standard* has decided to pursue the policy of presenting its readers with systematic surveys of scientific research and progress by means of special articles, reports of the proceedings of learned societies, and in other ways. An article upon the place of research in education was contributed by Principal Miers, F.R.S., to Monday's issue (November 1), and Sir Joseph Thomson will discuss the research degree and its working at Cambridge in an article which will appear on the first Monday in December. Particular attention is to be given to research facilities and results, and the intention of the scheme is to make the public realise what the scientific spirit signifies and what is being done by it for the advancement of natural knowledge. Such efforts to direct public attention to the aims, methods, and conclusions of science should lead to increased recognition of the national value of research and higher education. We shall watch the experiment with interest, and in the hope that it will meet with unqualified success.

October was a wet month in nearly all parts of the British Isles, but the excess of rain was due to the remarkable falls which occurred during the closing week, when the south and east of England, especially, came under the influence of a cyclonic disturbance which, for a time, remained fairly stationary over the entrance of the English Channel. The weather report for the week ending October 30, just published by the Meteorological Office, shows that at Broadstairs the total for the period was 6·03 inches, and in three days the rain yielded 5·79 inches; at Margate the total for the week was 5·68 inches, and at Brighton 5·15 inches. On one day in the middle of the week the rainfall at Brighton measured 3·32 inches, at Broadstairs 2·93 inches, at Margate 2·73 inches, and at Shoeburyness 2·50 inches. Some remarkable falls have undoubtedly occurred, but it is rather too early for an exact statement of facts. The aggregate rainfall for the month is reported as 9·82 inches at Shanklin, 9·40 inches at Southampton, and more than 8 inches at Brighton and Bournemouth. At Valencia the total rainfall for October is 8·06 inches, and rain fell every day with three exceptions; at Jersey the total was 7·14 inches. At Greenwich the aggregate measurement for the month is 4·07 inches, whilst the average for October during the last half-century is 2·78 inches, and rain fell on twenty-two days. In 1880 the October rainfall at Greenwich was double the measurement for last month. At several places in Scotland and in the north of England the rainfall for October was slightly less than the average. The month was unusually mild, and the duration of bright sunshine varied considerably in different parts of the country.

In his presidential address to the Institution of Civil Engineers on Tuesday, November 2, Mr. J. C. Inglis did not deal with any particular engineering subject, but rather commented upon the recent activities of the institution, the professional status of the engineer, and the position he occupies in relation to certain economic questions of the day. Referring to the new by-laws and regulations drawn up with the object of securing a higher and more efficient standard of training than has hitherto been required, Mr. Inglis pointed out that there still appears to linger a certain popular confusion of ideas regarding knowledge which can be tested by question and answer in ordinary examination papers, and ability to apply such knowledge intelligently to the practical problems of every-day professional life. The Institution of Civil Engineers, differing perhaps in degree, though not, it is thought, in principle, from the views sometimes entertained by other bodies on this subject, has persevered throughout in the belief that for success in the application of the great powers of nature to the use and convenience of man, there can be, as a rule, no efficient substitute for regular training under those who are practising that art; albeit, the foundation of intelligent work in this direction lies in the possession of sound education and appropriate scientific knowledge. The successful engineer of the future must possess in an increasing degree a thorough knowledge of the principles of design, of the materials to be used, and their behaviour when in use (keeping in view the facility and cost of repairs), and of the actual working conditions affecting the life of the structure or plant or machine designed. The engineer should not only know how to design his works, but be familiar with the conditions under which they are to be used. The practical engineer of the early part of the nineteenth century built up his theory from his personal experience, and applied his self-taught theories according to his judgment. The practical engineer of the twentieth century is he who, knowing the theoretical principles of his profession, employs as data the facts gathered from his experience, and whose generalisations from such experience merely consolidate his knowledge of principles.

Naturen for October contains an appreciative memoir by Mr. P. R. Sollied, accompanied by a portrait, of Emil Christian Hansen (1842–1909), with an account of his bacteriological researches.

We have received a specimen copy of the first part of "Coleopterum Catalogus," edited by Mr. S. Schenkling, and published by W. Junk, of Berlin, this part being the work of Mr. R. Gestro, and dealing with the family Rhysodidæ. Full synonymy of the families, genera, and species is given, but there are no diagnoses. An index of the species of this family is given at the end of the part.

To the October number of the *Zoologist* Mr. A. H. Patterson communicates the first part of an interesting account of the fisheries and fish of east Suffolk, with special reference to the takes of herring and mackerel at Lowestoft. In regard to the apparently capricious movements of the shoals of mackerel, the author expresses the opinion that these are entirely due to tidal and other influences affecting the natural economy of the species.

In their report for the year ending June 30, the members of the committee of the Manchester Museum put on record their regret at the resignation of Dr. W. E. Hoyle, who held the office of keeper (a title latterly changed to director) of the establishment for the long period of twenty years. Dr. Hoyle resigned on March 25, when he was appointed director of the National Museum at Cardiff. Among important additions to the museum during the year under review, reference may be made to a collection of fossil fishes made by the late Mr. John Ward.

According to the *Museum News*, the authorities of the Children's Museum at Bedford Park, Brooklyn, have been devoting their attention during the past summer to exhibits illustrative of the Hudson-Fulton celebration. A large series of the animals inhabiting the country at the time of Hudson's visit has been placed on exhibition, with special notes to those which are now on the point of disappearing or which have been already exterminated. Such species of trees growing in the museum gardens as were native to the country in Hudson's time have also been marked with special labels.

It is satisfactory to learn from the September number of the *Victorian Naturalist* that the colony of sea-lions on "Seal Rocks," in Bass Strait, continues to flourish under Government protection. In November, 1908, a party of naturalists left Melbourne for a cruise in Bass Strait, and one of their number gives the following account of their visit to the sea-lions:—"As we approached this haunt of the seals, hundreds of the animals could be seen in the water, and from the rocks came, borne on the wind, the sound of their voices. The rookery presented a 'moving spectacle,' as we surveyed it through binoculars from the steamer's deck. Huge brown forms were clambering among the pools and darting in and out of the surf, while sleek cubs lay basking in the sunlight beside their anxious mothers." In the same issue attention is directed to the serious destruction now being inflicted on the native bird-fauna of the country by the progeny of introduced European foxes.

In vol. cxviii., part i., of the *Sitzungsberichte der k. Academie der Wissenschaften*, Prof. O. Abel gives a restoration of the skeleton of *Eurhinodelphis cocheteuxi*, of the Belgian Upper Miocene, in which the prolongation of the toothless rostrum far in advance of the lower jaw is well shown. The length of the figured skeleton, which is probably that of a male, is nearly 16 feet, but the majority of specimens are smaller. From the strong development of the caudal vertebræ, indicative of powerful tail-muscles, the author infers that these cetaceans were swift swimmers, while the free cervical vertebræ permitted, as in the fresh-water Iniidæ and Platanistidæ, of considerable movements of the head. These circumstances, taken in connection with the long edentulous rostrum, projecting far in advance of the lower jaw, and the weak state of the dentition generally, suggest that these long-snouted dolphins swam on the surface of the sea, where they captured their food—probably fishes—in much the same manner as does the skimmer (Rhynchops) among birds. Dr. Abel also describes the skull of *Saurodelphis argentinus* from the Argentine Pliocene, and shows that the genus was nearly allied to the existing Amazonian Inia.

The brain of the late Prof. D. J. Mendeléeff, the chemist, has been investigated and described by Profs. W. von Bechterew and R. Weinberg. The results of their investigation, with eight finely finished plates, form the first of a series of monographs dealing with the anatomy and development of the body, which is to be edited by Prof. Wilhelm Roux, of Halle, and published by Mr. W. Engelmann, of Leipzig. The size of the great chemist's brain was above the average, but not remarkably so; its weight was 1571 grams. The convolutions are simple in their arrangement; indeed, no one, from a mere examination of the organ, could have formed any opinion—at least in our present state of knowledge—as to the very special qualities manifested by it in life. Only two features were in any degree peculiar—a highly convoluted part of the left parietal lobe and a comparatively small and simple temporal lobe. Profs. Bechterew and Weinberg have made a very welcome addition to the limited number of descriptions of the genius-brain, and if at present the results of their labour appear to be negative, the day may soon come that will provide a key to the facts which they have been content merely to tabulate and to describe accurately.

Prof. E. Gaupp, of Freiburg, has devoted the fourth part of the "Sammlung anatomischer und physiologischer Vorträge und Aufsätze" to the consideration of the asymmetry of the human body (Jena: Gustav Fischer). From a consideration of the literature dealing with this matter, he has come to the conclusion that asymmetry in the right and left halves of the body is normal, and is to be regarded, not as a defect, which was the opinion formulated by Bichat a century ago, but as an advance and sign of specialisation. The asymmetry of the skull, face, jaws, spine, chest, pelvis, and limbs is not present at birth; it appears as the individual becomes adapted to his surroundings. The asymmetry is not a question altogether of right- or left-handedness or right- or left-brainedness; in Prof. Gaupp's opinion the tendency to a right- and left-sided specialisation is inborn in the individual. The asymmetry is simply exaggerated by the reaction of use and disuse. Classical sculptors represented in their work a degree of asymmetry of the face equal to that seen in modern races. The greater the degree of asymmetry the higher the point of evolution. Prof. Elliot Smith found that the hemispheres of the negro brain, and especially those of the anthropoids, showed a smaller degree of asymmetry than those of European races.

An article by Mr. B. L. Issatchenko, continuing two earlier communications on the conditions for chlorophyll formation, is published in the *Bulletin du Jardin Impérial Botanique*, St. Petersburg (vol. ix., part v.). The author states that a low temperature (−8° C.) does not prevent the formation of chlorophyll, and that it is formed in plants as quickly at a low temperature as a high one, the formation of the pigment depending exclusively on the strength and duration of the light. According to other results obtained, the formation of chlorophyll continues in the presence of the vapour of formaldehyde or chloroform.

Dr. F. Krasser has prepared for publication a series of diagnoses, left by the palæontologist Stur, of some fossil plants found in Triassic beds at Lunz, in Lower Austria, that are assigned to the filicinean family Marattiaceæ. Seven genera and seventeen species are confirmed by Dr. Krasser, of which one genus, Speirocarpus, and ten species are new to science. Five of the genera go back to the Palæozoic, but Speirocarpus and Bernoullia have only been found in Mesozoic strata. The article appears in the *Sitzungsberichte der kaiserlichen Akademie der Wissenschaften*, Vienna (vol. cxviii., part i.).

Further information regarding the curious herbaceous Ecanda rubber plant, *Raphionacme utilis*, is published in the *Kew Bulletin* (No. 8). The plant grows abundantly on a plateau in the district of Bihé, Portuguese West Africa; it produces a short leafy shoot and a good-sized tuber, from which the rubber is obtained. The tubers vary in weight up to 5 lb., and occasionally exceed this measure. It seems probable that there may be more than one species. The plants can be propagated from seed, but take several years to reach a marketable size. In the same number of the Bulletin there appears a short note, by Mr. J. M. Hillier, with reference to a new rubber plant, *Asclepias stellifera*. The identification refers to samples of root rubber forwarded by Mr. J. Burtt Davy from the Transvaal, one of which was reported to be of good quality.

A fact of peculiar interest in connection with plant distribution is presented by Dr. Engler in the discovery, announced in his *Botanische Jahrbücher* (vol. xliii., part iv.), of an African plant referred to the family Triuridaceæ. The plants of this family are saprophytes of such a reduced nature that there is some doubt whether they are correctly classed with monocotyledons. Several species, under two genera, have been discovered in tropical America and tropical Asia; also a new species from the Seychelles islands was described by Mr. Botting Hemsley in 1907. The latest species was collected in West Africa, in the Cameroons, so that the genus Sciaphila is now recorded from three continents. It is quite unlikely that the seeds of a plant which is a saprophytic inhabitant of virgin forest should be transported by water, and the problem of its existence in these distant isolated localities is exceedingly puzzling. An anatomical examination of the stem showed a reduced structure not inconsistent with a monocotyledonous position.

Under the subtitle "Les Districts littoraux et alluviaux," the Jardin botanique de l'État has issued, with the authority of the Belgian Ministère de l'Intérieur et de l'Agriculture, the first portion of a work on "Les Aspects de la Végétation en Belgique," by Profs. C. Bommer and J. Massart. The studies of these two authors in this field, the results of which have appeared in the pages of the *Bulletin de la Société royale de Botanique de Belgique*, are already well and favourably known. In a brief *résumé* Prof. Th. Durand, director of the Brussels Botanic Garden, explains the object the authors have in view, and informs us that the work, in its complete form, will include some 400 plates distributed in five parts, as follows:—i., Districts littoraux et alluviaux, by Prof. Massart; ii., Districts flandrien et campinien, by the same author; iii., Districts argilo-sablonneux et crétacé, by Prof. Bommer; iv., Districts calcaire et jurassique, by Prof. Massart; and v., District ardennais, by Prof. Bommer. The work will include in its scope the illustration both of the cultivated and of the uncultivated portions of Belgian territory, and will endeavour to give a complete picture of the vegetation of the whole country. The method adopted by the authors in preparing their illustrations has involved their securing photographs on plates measuring 30 cm. by 40 cm. With the object of rendering available for independent use the more important of these plates, it has been resolved to issue a reduced edition containing about one-fourth of the plates in the complete work. The copy of this reduced edition of the first volume, now under notice, contains twenty-four plates as against eighty-six plates in the complete edition of the same volume. These plates are excellent reproductions from photographs of great beauty. They largely explain themselves, and are highly instructive. The accompanying letterpress is reduced to a brief amplification, in three pages, of the systematic summary of the plates, whereof 1 and 2 illustrate the District des Estacades et Briselames; 3–9, the District des Dunes littorales; 10–13, the District des Alluvions marines; 14 and 15, the District des Alluvions fluviales; 16–22, the District des Polders argileux; while 23 and 24 illustrate the District des Polders sablonneux et des Dunes internes.

The thirty-first and thirty-second reports of the Connecticut Agricultural Station for the years 1907–8 form a volume running into nearly a thousand pages. A considerable amount of space is devoted to the reports from the analytical laboratories, where large numbers of foodstuffs intended for human consumption are investigated in addition to the ordinary agricultural materials. In accordance with the American system, results of the analysis are published, together with the trade name of the article, the manufacturer, the dealer, the price, and the guaranteed composition, so that one can see at a glance which articles are above and which below their guarantees. Dr. Osborn, head of the laboratory for the study of proteids, reports that he has isolated a new substance from one of the wheat proteins, a di-peptide of proline and phenyl-alanine. This substance is important, not only in connection with the structure of wheat protein, but in connection with the chemistry of proteins in general. Quantitative determinations have also been made of the amounts of decomposition products of various vegetable proteins. The entomological department has spent much effort in subduing the gypsy moth at the only place in the State where it was found. The infected area was isolated by destroying the shrubs and bushes on all sides of it as far as possible; within the area all larvæ, pupæ, and egg-masses discovered were destroyed; 14,000 trees were banded and inspected daily. A new orchard pest, the peach saw-fly, which threatened great injury, was completely controlled by spraying with lead arsenate. In the agricultural department a number of experiments are recorded on the hybridisation of potatoes. The botanist records studies of the "calico" disease of potatoes, and chlorosis in other plants, the downy mildew of Connecticut, the root rot of tobacco caused by the fungus *Thielavia basicola*, and of certain heterœcious rusts of Connecticut having a peridermium for their œcial stage. The forester has carried out experiments on the economical planting of white pine, on different methods of seeding and planting forest trees, on the fertilisation of young trees by growing cow peas, on the progress of the white pine disease, and on methods of treating the pine weevil. The increased interest in forest planting in Connecticut is shown by the fact that about 100,000 forest trees were planted in 1906, 350,000 in 1907, and 600,000 in 1908. A forest survey is in hand, and a fire service has been organised.

Prof. L. Duparc, assisted by Dr. Francis Pearce and Madame Tikanowitch, his colleagues in the University of Geneva, has issued the third and concluding part of his "Recherches géologiques et pétrographiques sur l'Oural du Nord; le Bassin de la haute Wichéra" (*Mémoires de la Société phys. et d'Hist. nat. de Genève*, vol. xxxvi., fascicule i., July, 1909, price 20 francs). The results of three expeditions, from 1904 onwards, are here reviewed, and the igneous and metamorphic rocks are described in considerable detail. The region lies on the west side of the Urals and north of Solikamsk, where numerous streams unite, flowing from a broad basin, to form the Vishera River, which in turn flows into the Kama, and thus into the Volga system. The plateaus, covered with stones and showing few good rock-exposures, represent a mass uplifted during the Hercynian earth-movements, and subjected to prolonged denudation. Interesting terrace-structures, preserved only among the hard quartzitic ranges, point to ancient epochs of erosion under conditions different from those of the present day. Successive terraces rising above one another, and apparently independent of tectonic structure, offer a problem which Prof. Duparc is compelled to leave at present unexplained. They certainly suggest, in the numerous sketches given, relics of abnormally large terraces of marine erosion rather than uplifted peneplains. Among the petrographic descriptions we note that a highly pleochroic amphibole, associated with magnetite, occurs in one of the ore-materials; the authors believe this to be a new species, and have elsewhere given it the name of "Tschernichéwite." Its characters are as yet incompletely determined; if we may judge from those here given, its weak birefringence seems to ally it to riebeckite, while its axial plane is in an unusual position for an amphibole, and its pleochroism is near that of glaucophane. The iron mines of the district are carefully described, and the memoir is well illustrated by photographic views and effective drawings of broad landscapes.

IN the *Reliquary* for October Mr. T. Sheppard, curator of the Municipal Museum, Hull, records the discovery at Malton, in Yorkshire, of two interesting bronze statuettes, one, the more primitive of the two, representing Hercules bearing the skin of the Nemean lion, the other Venus. They probably belong to the third century A.D., and may have been lost or buried at the time the Roman legionaries were withdrawn from Britain.

THE Meteorological Chart of the North Atlantic Ocean for November, issued by the Meteorological Committee, contains an account of a West India hurricane experienced by the ship *Barranca* (Captain W. Long) in August last. At noon on August 15 she was in 24° 42′ N., 57° 1′ W., with a falling barometer and strong easterly breeze. At 4 p.m. the barometer failed to respond to the diurnal range, which showed that a storm was not far distant. On the morning of August 16 the ship met the full force of the hurricane, and at 2h. p.m. the sea was "like a boiling cauldron." Next day the east wind veered to south-west, and the ship's position at noon was 22° 43′ N., 61° 44′ W., having apparently drifted some 100 miles to the north, out of her south-west course, in two days. Owing to careful navigation, in accordance with the rules laid down in the "Barometer Manual" issued by the Meteorological Office, the only damage sustained by the ship was a severe straining.

IN the *Rendiconti della R. Accademia dei Lincei* (vol. xviii., 1909) Dr. F. Eredia publishes an interesting preliminary note on the frequency of wind-direction in central Italy. The discussion shows clearly the different effects of the two slopes which divide the country from the Adriatic and Tyrrhenian Seas. Winds from N.–E. prevail along the Adriatic slope in summer and along the Tyrrhenian slope in winter, and winds from S.W.–N.W. predominate in winter along the Adriatic slope and in summer along the Tyrrhenian slope; thus, while one direction has its maximum of frequency on one slope, it has its minimum along the other. The author endeavours to explain these facts and to compare them with the theoretical laws of the circulation of the atmosphere.

A VALUABLE series of articles on life in the various colonies and other countries in which many of our young electrical engineers obtain posts has appeared in the *Electrical Review* during the last two months. Although intended, in the first instance, for electrical engineers, they will prove of great value to all who have thoughts of taking up appointments abroad, as they are in every case by men with practical experience of the countries about which they write. Each article deals with the climate of the country, the cost of living, the salaries, and the ultimate prospects of those taking up posts open to Europeans.

THE vacuum vessel introduced by Dewar has proved of such value as a means of improving the thermal insulation of bodies that it is no surprise to find it introduced into calorimetry. At the suggestion of Prof. Nernst, of the University of Berlin, Dr. H. Schottky has carried out a series of measurements with a modified form of Favre and Silbermann calorimeter, in which the mercury was replaced by pentane and the bulb of the calorimeter surrounded by a vacuum vessel. The instrument looks like a Bunsen ice calorimeter using pentane instead of ice, and having a vacuum vessel around its bulb. It has proved a great improvement on its predecessors, and is considered by Dr. Schottky to be extremely accurate. A full description appeared in the *Physikalische Zeitschrift* for September 15.

WE have received separate copies of a number of papers which have been written by the staff of the Physikalisch-technische Reichsanstalt, and have appeared in the *Annalen der Physik* and other periodicals during the past few months. Two of them deal with optical subjects, and are of special interest. In the first place, it has been found by Drs. E. Gehrcke and G. Leithauser that it is possible to convert a celluloid copy of a diffraction grating, such as have been made by Thorpe, of Manchester, for some time, into a reflecting grating by dusting it with kathode particles in a vacuum. The process gives gratings which are almost as good as the original. Further, Dr. L. Janicke has been investigating the properties of the spectral lines of the metallic elements by the high dispersion obtainable with the Lummer-Gehrcke plate spectroscope, and gives the wave-lengths of the sharp lines of the spectra of fourteen elements, which were used as the anodes of arcs burning *in vacuo*.

AT a recent meeting of the Association of Municipal and County Engineers a paper was read on the "G.B." tramway system and its results in Lincoln by Mr. S. Clegg, the city electrical engineer. The author stated that during the first twelve months a total of seventy-one live studs was recorded, these being mostly owing to defects in details in the original construction. The old type of cable had been completely replaced in 1908, and the average at present is about three live studs per month. Mr. Clegg considers that there is less danger to the public from shock and personal injury with the "G.B." system than with the overhead system. Studs which had become alive at Lincoln had always been located as soon as they occurred without danger to anyone.

Commenting on the aviation meetings at Doncaster and Blackpool, *Engineering* for October 22 directs attention to the advantages of the monoplane from the point of view of transport from place to place. The frame consists simply of the backbone carrying the engine, driving-seat, and controlling gear, together with the wheels on which the machine runs when on the ground. This can be sent complete in one piece, the main wings and the horizontal and vertical rudders being detached for the purpose. The wings are attached very easily by means of sockets on the backbone and by wire ties. In the case of one competitor, whose main wings had not arrived until late in the morning, these were all fixed up in about an hour. Probably with more experience it will be possible to design a monoplane which can be taken to pieces or erected complete in an hour or two. The biplane, having more numerous tie-rods, appears to require much larger packing cases or more time for its erection, according to the extent to which it is taken to pieces. In the air the biplanes certainly appear to be more steady than the monoplanes, the latter occasionally flying in a series of dips, especially when near the ground. When high up, however, the monoplane appeared very steady.

While remarking on the enormous advance which has been made in aviation, *Engineering* points out that the motors have very far from the trustworthiness required for practical work, and each machine had several mechanics in attendance on it. The engines at present in use require a large amount of attention. This is a matter which should be capable of amendment. The other limitations which require attention are the incapacity for flying in bad weather and for alighting on rough ground. To be of any practical use, aëroplanes should be capable of alighting and starting from an ordinary grass or stubble field, and there does not seem the least difficulty in arranging for this; in fact, the combination of runners and wheels on the Farman machine would probably be satisfactory. Flying in a wind may possibly be largely a matter of practice and confidence, and it is quite possible that, with very little alteration in the machines, men will learn to fly in any reasonable weather.

Erratum. In the article upon the magnetic results of the *Carnegie* (October 28, p. 532, col. 2, line 3 from bottom) Dr. Bauer should have written $\frac{1}{2}^{\circ}$ instead of $\frac{1}{2}'$, which was the value given in the typewritten communication received from him and printed in Nature.

OUR ASTRONOMICAL COLUMN.

Changes on Mars.—Another large prominence on the terminator of Mars is announced by M. Jarry-Desloges in No. 4364 of the *Astronomische Nachrichten* (p. 335). This object was seen on the night of October 14–15 in the region of Phaëthontis, which itself was very white; this whiteness of Phaëthontis, and similar regions near the limb, was remarked by the Rev. T. E. R. Phillips in his observations of 1903.

A drawing of the planet, as it was seen by M. Antoniadi with an 83-cm. reflector on September 20, is published as a frontispiece to No. 10, vol. iii., of the *Rivista di Astronomia* (Turin).

Halley's Comet.—In No. 4364 of the *Astronomische Nachrichten* (p. 333, October 20) Prof. Wolf publishes the position of Halley's comet as determined from a plate taken on October 10, and states that, with a power of 140 used on the reflector, he is able to see the comet as a small nebulous patch; but it is on the limit of visibility with this instrument, its magnitude being given as 14·5.

In the same journal (p. 335) Mr. Knox Shaw gives positions determined from photographs taken at the Helwan Observatory on September 13, 15, and 16 respectively.

An interesting popular article, dealing with the history and nature of the comet, appears in part cxliii. of *Chambers's Journal* (p. 710, November 1) from the pen of Dr. Alex. W. Roberts.

Sun-spot Spectra.—A summary of the results so far obtained from the study of the photographs of sun-spot spectra, taken at the Mount Wilson Observatory, is published by Prof. Adams in No. 2, vol. xxx., of the *Astrophysical Journal* (pp. 86–126, September).

The paper is too comprehensive for adequate summary in these columns, where many of the details have already appeared, but the various tables given will prove interesting and instructive to all workers in this branch of solar physics.

Prof. Adams believes that the intensification of various solar lines in the spot spectrum is due to the lowering of temperature, and not, in general, to a variation of pressure. Investigations at Mount Wilson, where a shift of 0·003 or 0·004 Å. could be detected, indicate that the excess of pressure in spots, over that on the surface of the sun, can hardly be so great as one atmosphere. A study of the enhanced lines, based mainly on the tables published by Lockyer, shows that of 144 such lines 130 are distinctly weakened, while fourteen show no change, in passing from the Fraunhoferic, to the spot, spectrum.

The lines of each element are studied *seriatim*, and of the lines of iron given by Rowland, 784, or 71 per cent., are affected in the spot spectrum; of the 558 lines due to iron alone, 300 are strengthened and 258 weakened in passing from the solar to the spot spectrum. The behaviour of the iron lines is best explained by the decrease of temperature in the spot.

The greater part of the unknown fluting, and band, lines in the spot spectrum may be accounted for by the presence of the titanium oxide, "magnesium hydride," and "calcium hydride" spectra, whilst the lines that are widened without marked increase of intensity are sufficiently explained by the existence of a magnetic field in sun-spots.

Designations of newly discovered Variable Stars.—The committee for the A.G. Catalogue of Variable Stars publishes the permanent names of sixty-two recently discovered variables in No. 4364 of the *Astronomische Nachrichten*. The provisional name, permanent designation, position, and magnitude range are tabulated for each object, and a series of notes gives particulars of discovery and subsequent observations.

The Motions of Some Stars in Messier 92 (Hercules).—Prof. Barnard discusses the proper motions of certain stars in the cluster M. 92 in a paper appearing in No. 4363 of the *Astronomische Nachrichten*.

Micrometer observations of this cluster were made by Schultz, at Upsala, about 1873, and results were published for thirty-seven stars. These results, when compared with those obtained from a photograph taken in 1898, led Dr. Bohlin to the conclusion that some of the stars exhibited large proper motions during the twenty-five years' interval, but Prof. Barnard suggested that Schultz's observations of faint objects with a 9-inch telescope were probably not sufficiently exact to permit of this deduction; measurements of two photographs, taken with an interval of eight years between them, confirm the suggestion.

There are two stars, however, which show decided motions during the eight-year interval, one being No. 11 and the other a fainter star temporarily designated a. The former has an annual motion of 0·085″ in position angle 220° (8·5″ per century), and the second an annual motion of 0·065″ in position angle 181·4° (6·5″ per century). Prof. Barnard concludes that another fifty years should show motion in many of the stars of this cluster, whilst within a few hundred years it will be possible to investigate the laws which control the motions of this and similar great and crowded masses of stars. A carefully oriented reproduction of a photograph of M. 92, taken with the 40-inch telescope, accompanies the paper, and will facilitate further work on this interesting cluster.

SOLAR VORTICES AND MAGNETIC FIELDS.[1]

I HEARTILY appreciate the privilege of describing in this lecture-room some of the recent work of the Mount Wilson Solar Observatory. Like so much of the scientific research of the present day, it goes back for its origin to the fundamental investigations of English men of science. The spectroheliograph, which tells us of the existence of solar vortices, is a natural outcome of the application of the spectroscope in astronomy, where Englishmen were foremost among the pioneers. The detection of a magnetic field within these vortices followed directly from Zeeman's beautiful discovery of the influence of magnetism on radiation—a logical extension of the earlier work of Faraday—and from the classic investigations of Crookes and Thomson on the nature of electricity. In reviewing these great advances, investigators in other lands must again and again wonder at the exceptional ability of the English mind to make fundamental discoveries. When these discoveries have been made it is a comparatively simple matter to utilise them in many departments of science. Americans cannot fail to rejoice that they may share in the traditions of a race which counts among its members the men who have given the Royal Institution its fame.

It is customary to distinguish sharply between the observational and experimental sciences, including astronomy in the former. In physics or chemistry the investigator has the immense advantage of being able to control the conditions under which his observations are made. The astronomer, on the other hand, must be content to observe the phenomena presented to him by the heavenly bodies, and interpret them as best he may. I wish to emphasise the fact, however, that the distinction between these two methods of research is not so fundamental as it may at first sight appear. In 1860 a laboratory, in which experiments were conducted for the interpretation of astronomical observations, was established by Sir William Huggins on Upper Tulse Hill. The advantage of imitating celestial phenomena under laboratory conditions was thus appreciated half a century ago. I shall indicate later how important a part such a laboratory plays in the work of the Mount Wilson Solar Observatory. I shall also show that in other ways the astronomer may advantageously follow the physicist, particularly in the choice of observational methods and in the design of instruments of research.

Sun-spots were discovered as soon as Galileo and his contemporaries directed their little telescopes to the sun. In fact, ancient Chinese records indicate that spots of exceptional size had been detected by the naked eye many centuries before. Long after their discovery, the most diverse views were held as to the nature of sun-spots. Sir William Herschel mentioned the uncertainty which had existed prior to his time, remarking that the spots had been variously described as solid bodies revolving about the sun, very near its surface; the smoke of volcanoes; smoke floating on a liquid surface; clouds in the solar atmosphere; the summits of solar mountains, uncovered from time to time by the ebb and flow of a fiery liquid, &c. In Herschel's own view the spots are to be considered as the opaque body of the sun seen through openings in the luminous atmosphere which envelops it. Indeed, he considered that the sun should be regarded as the primary planet of our system, and even suggested the probability that it is inhabited. "Whatever fanciful poets might say, in making the Sun the abode of blessed spirits, or angry moralists devise, in pointing it out as a fit place for the punishment of the wicked, it does not appear that they had any other foundation for their assertions than mere opinion and vague surmise; but now I think myself authorised, *upon astronomical principles*, to propose the Sun as an inhabitable world, and am persuaded that the foregoing observations, with the conclusions I have drawn from them, are fully sufficient to answer every objection that may be made against it."[2]

Sir John Herschel did not abandon the idea of an opaque solar globe, but suggested that hurricanes or tornadoes might account for the piercing of the two strata of luminous matter which ordinarily conceal this globe. "Such processes cannot be unaccompanied by vorticose motions, which, left to themselves, die away by degrees and dissipate—with this peculiarity, that their lower portions come to rest more speedily than their upper, by reason of the greater resistance below, as well as the remoteness from the point of action, which lies in a higher region, so that their centre (as seen in our water-spouts, which are nothing but small tornadoes) appears to retreat upwards. Now, this agrees perfectly with that which is observed during the obliteration of the solar spots, which appear as if filled in by the collapse of their sides, the penumbra closing in upon the spot, and disappearing after it."

We now know that sun-spots are brighter than the brightest arc light, and that their apparent darkness is merely the result of the contrast with the intensely brilliant surface of the photosphere. We also know that the sun is a gaseous globe, attaining a temperature of about 6000° at its surface, and perhaps millions of degrees at its centre. If we examine a large-scale photograph of a sun-spot we see that it consists of a dark central region, called the umbra, and a surrounding area, decidedly less dark, called the penumbra. The structure of a spot, as this admirable photograph by Janssen shows, is granular, like that of the photosphere. In the penumbra these granulations seem to group themselves more or less radially, as though under the influence of some force directed toward or away from the umbra. Unfortunately, direct photographs of the sun have not yet attained such perfection as to show the most minute details of sun-spots. To appreciate these, we must have recourse to the exquisite drawings of Langley, the truthful quality of which is recognised by every astronomer who has observed sun-spots under favourable conditions. We shall see that the characteristic structure represented by these drawings is repeated, on a far greater scale, in the higher regions of the solar atmosphere disclosed on recent spectroheliograph plates.

Since the time of Sir John Herschel, many astronomers have proposed vortex theories of sun-spots. One of the first of these is the theory of Faye, who supposed the whirling motion to be the direct result of the peculiar law of the sun's rotation. This law was discovered by Carrington, who found from observations of spots near the equator that the sun completes a rotation in about twenty-five days, while the motion of spots at a latitude of 40° indicated the time of rotation to be nearly two days longer. Thus, as the rotation period increases toward the poles, the photosphere at the northern and southern boundaries of a sun-spot must move at different velocities (assuming the law of the sun's rotation to be the same as that of the spots). This difference in velocity would tend to set up whirling motions, clockwise in the southern hemisphere and counter-clockwise in the northern hemisphere. Sun-spots, in Faye's opinion, are the visible evidences of such whirls.

This theory has had many supporters, but it is now generally agreed that the difference in the rotational velocity of adjoining regions of the photosphere is not nearly sufficient to account for the observed phenomena. Secchi, one of the most assiduous observers of solar phenomena, was strongly opposed to Faye's theory. He pointed out that about 6 per cent. of the spots he observed gave some evidence of cyclonic action, but in the vast majority of cases such forms as Faye's theory seemed to demand were lacking. We nevertheless owe to Secchi a most striking drawing of a sun-spot vortex.

When the spectroheliograph was first systematically applied to solar research in 1892, many rival theories of sun-spots occupied the field. Since the function of this instrument is to photograph the phenomena of the invisible solar atmosphere, it might be hoped that the results would throw much light on the nature of sun-spots. For many years, however, this hope was not realised. The first monochromatic images of the sun were made with the K line of calcium. If we compare such an image with a direct photograph of the sun, made in the ordinary way, we see that the sun-spots are surrounded and frequently covered by vast clouds of luminous calcium vapour. These attain elevations of several thousand miles above the sun's surface, but they must not be confused with the prominences, which ascend to much higher elevations. When observed at the sun's limb, the bright calcium flocculi, as these luminous clouds are called, are so low, in comparison with the prominences, that they can hardly be detected as elevations. Thus our knowledge of the calcium flocculi must be derived mainly from the study of spectroheliograph plates, which show them in projection on the disc. I must not omit to mention, however, that the calcium vapour rises to the highest parts of the prominences, and that this higher and cooler vapour frequently indicates its presence on spectroheliograph plates in the phenomena of dark flocculi. These are relatively inconspicuous, however, and need not be discussed here.[1]

---

[1] Discourse delivered at the Royal Institution on Friday, May 14, by Prof. George E. Hale, For.Mem.R.S.

[2] William Herschel, "On the Nature and Construction of the Sun and Fixed Stars," p. 20.

It soon appeared that the average photograph of bright calcium flocculi could not be counted upon to indicate the existence of definite streams or currents in the solar atmosphere. In 1903 the hydrogen flocculi were photographed for the first time. By comparing these flocculi with the corresponding calcium flocculi we see that, in general, dark regions on the hydrogen image agree approximately in form with bright regions on the calcium image. This might appear to indicate that hydrogen is absent in the regions where calcium is most abundant. An investigation of the question, however, does not lead to this conclusion. Dark hydrogen flocculi seem to mark those regions on the sun's disc where hydrogen is present as an absorbing medium, which reduces the intensity of the light coming through it from below. In certain areas, where the temperature is higher or the condition of radiation otherwise different, the hydrogen flocculi are bright. In many cases eruptions are in progress at these points, but in others the difference in brightness is apparently not the direct result of eruptive action.

The hydrogen flocculi, thus photographed with the lines Hβ, Hγ, or Hδ, differ in many respects from the calcium flocculi. Not only do they usually appear dark, where the calcium flocculi are bright: their forms exhibit striking peculiarities, which are absent or much less conspicuous in the case of calcium. The appearance of the calcium flocculi resembles that of floating cumulus clouds in our own atmosphere; their capricious changes in form reveal the operation of no simple law. But the hydrogen flocculi, on the contrary, exhibit a definiteness of structure in striking contrast to this appearance. Some of the photographs strongly remind us of the distribution of iron filings in a magnetic field, and suggest that some unknown force is in operation.

Such was the condition of the subject when the red Hα line of hydrogen was first applied to the photography of the flocculi, on Mount Wilson, in March, 1908. The calcium and hydrogen flocculi had been studied for several years, and much had been learned as to their nature and their motions. It had been found, for example, that the calcium flocculi observe the same law of rotation that governs the motions of sun-spots, while the hydrogen flocculi apparently follow a different law, in which the decrease in the angular rotational velocity from the equator toward the poles is much less marked. The latter result is in harmony with the investigations of Adams, whose accurate measures of the approach and recession of the hydrogen at the eastern and western limbs of the sun offer but little evidence of equatorial acceleration on the part of this gas. For this and other reasons it had been concluded that the hydrogen shown in such photographs reaches a higher level than the vapours of the bright (H_2) calcium flocculi. The region of the atmosphere previously explored with the spectroheliograph was nevertheless confined (except in the case of eruptions and dark calcium flocculi) to a comparatively low level, lying within a few thousand miles of the photosphere. What might be expected if a still higher region could be satisfactorily photographed in projection on the disc?

The red line of hydrogen offered the means of disclosing the phenomena of this higher atmosphere. As it may not immediately appear why different lines, caused by the radiation of the same gas, should not give precisely similar photographs, a brief reference to the aspect of a prominence in the red and blue hydrogen lines may be advantageous. Here are two photographs of the same prominence, seen in elevation at the sun's limb, one made with Hα, the other with Hδ. As the red line is very bright, even in the highest regions, the photograph taken with its aid shows the entire prominence. Hδ, on the other hand, is relatively weak at the higher levels, and consequently only the lower and brighter parts of the prominence are well recorded when this line is used. If, now, we suppose ourselves immediately above such a prominence, at a point where we observe it in projection against the disc, it is evident that the character of the hydrogen lines must depend upon their brightness at different levels. As we know that, speaking generally, absorption is proportional to radiation, the amount of light absorbed in the upper part of the prominence will be much greater for Hα than for Hδ. Hence the average level represented by the absorption of Hα will be higher than the average level represented by Hδ, since the higher gases play a more important part in the production of the former line. We may therefore expect that photographs of the sun's disc, taken with the light of Hα, will show the dark areas corresponding to absorption in the prominences much more clearly than photographs taken with Hδ. Moreover, since Hα is stronger than Hδ in the upper chromosphere, in regions where no prominences are present, the *average* level represented by this line will, in general, be higher than that represented by Hδ. A comparison of two photographs of the sun's disc, made with the lines in question, will suffice to make this clear. This enormous group of prominences, stretching for several hundred thousand miles across the sun, is much more clearly indicated by Hα than by Hδ. In general, the hydrogen flocculi are stronger and more distinct when photographed with Hα, and there are some regions which appear bright with Hα and dark with Hδ. This latter peculiarity probably has an important bearing upon the similar behaviour of hydrogen in certain stars and nebulæ, but a discussion of this question cannot be undertaken here.

FIG. 1.—Direct Photograph of Sun-spot Group. 1908, April 30, 6h. 25m a.m. Pacific Standard Time.

The first of the Hα photographs gave strong hopes of a substantial advance in our knowledge of the solar atmosphere. The sharpness and comparatively strong contrast of these flocculi, and the evidences of definite structure and clearly defined stream lines which they revealed, were highly encouraging. The work was begun during the disturbed weather of the rainy season, when the definition of the solar image is never of the best. On April 30, 1908, the first photographs were secured under the fine atmospheric conditions which prevail in the dry season. A direct photograph (Fig. 1) shows a small and insignificant group of sun-spots, which would not seem, without other indications, to merit special attention. The next photograph (Fig. 2) shows that an enormous calcium flocculus occupied this region of the sun, but its form was in no wise remarkable, and afforded no evidence of the phenomena brought to light by the Hα photograph. The structure recorded with the aid of the latter line (Fig. 3) recalls Langley's sun-spot drawings, and suggests the operation of some great force related to the sun-spot group. The same cyclonic structure had been less satisfactorily recorded on the previous day, but a comparison of the two photographs failed to indicate such changes as motion along the apparent stream lines might be supposed to produce.

---

[1] Eruptive prominences are also recorded on the disc as bright floccul'.

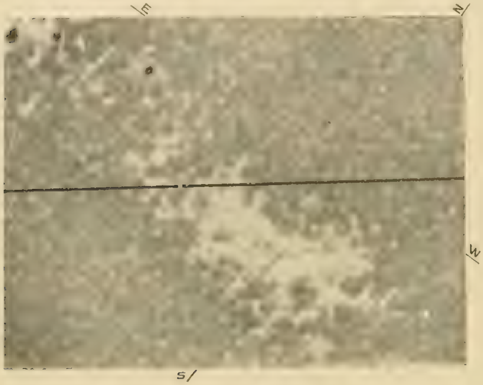

FIG. 2.—Same Region of the Sun, showing the Calcium (H_2) Flocculi. 1908, April 30, 4h. 43m. p.m. P.S.T.

The close of the rainy season now permitted an active study of the Hα flocculi to be undertaken. Many photographs were made daily, and the almost constant association of apparent cyclonic storms or vortices with sun-spots became evident. During several months of the year in California an unbroken succession of clear days can be counted upon, so that the changes of a given vortex can be followed without interruption. The cyclonic storms were found to be of two principal types, the first associated with groups of spots and represented in such photographs as those of April 30 and September 2, the second associated with single spots, and resembling a simple vortex, as illustrated in the photographs of September 9 and October 7, 1908 (Fig. 4). The appearance of these simple vortices is such as to indicate rotation in a clockwise direction in the southern hemisphere, and in a counter-clockwise direction in the northern hemisphere (assuming the direction of motion to be inward toward the spot). However, this cannot be taken as a general law, corresponding to the law of terrestrial cyclones. Indeed, many instances have been found of closely adjoining spots, in the same hemisphere and frequently in the same spot-group, having magnetic fields of opposite polarity, produced by vortices rotating in opposite directions.

In some cases, at least, these vortices seem to exercise a powerful attraction on the surrounding gases, as a series of photographs taken on June 3, 1908, illustrates. A long dark hydrogen prominence, first photographed in elevation at the sun's limb on May 28, had advanced half-way across the solar disc. It lay at the outer boundary of a well-defined vortex, centred on a sun-spot. This spot had been gradually separating into two parts, and on June 3 the separation was complete. The first photograph of a series of nine was made on this day at 4h. 58m. Several successive photographs indicated no appreciable change, but one taken at 5h. 07m. showed that the prominence was developing an extension toward the spot. At 5h. 14m. this had assumed the appearance illustrated in the next photograph, and eight minutes later, when the last photograph of this series was taken, the extension had almost reached the spot. It will be seen that it divided into two parts, which indicates that each umbra was a centre of attraction. The average velocity of the motion toward the spot was more than 100 km. per second. Later photographs, made on the following days, show a ring of bright hydrogen surrounding the spots, suggesting that the comparatively cool hydrogen carried down into the spots was re-heated and returned to the surface, after escaping from the lower end of the vortex. We thus seem to be observing some of the phenomena of an actual vortex in the sun; but it must not be supposed that cases of this kind are common. In many instances the hydrogen flocculi do not appear to move rapidly toward or away from spots, but undergo changes of intensity, as though the physical condition of the gas were constantly changing; but before proceeding further with a discussion of these sun-spot vortices, let us turn to another phase of the subject, which will afford much new information indispensable for this purpose.

We are all familiar with the effect produced by passing an electric current through a wire helix. The lines of force of the resulting magnetic field are parallel to the axis of the helix, and its intensity is determined by the diameter of the helix, the number of turns of wire, and the strength of the current. We also know, from Rowland's experiment, that the rapid revolution of an electrically charged body will produce a magnetic field. Thus, if a sufficient number of electrically charged particles were set into rapid revolution by the solar vortices, a magnetic field should result. What warrant have we for assuming the existence of charged particles in the sun, and how could such a field be detected?

Let me pass rapidly in review a series of phenomena with which you are all familiar. Sir William Crookes showed in this lecture-room, so long ago as 1879, that the negative pole of a vacuum tube sends out a stream of particles, capable of setting a light windmill in rotation, and deviated from their straight path when under the influence of a magnetic field. He has kindly consented to show the same tube again to-night; you now see the effect upon the screen. The recent work of Sir Joseph Thomson and others has proved that these are negatively charged particles, called "corpuscles" or "electrons," and that their mass is about 1/1700 of the mass of an atom of hydrogen. Moreover, Thomson has shown that at low pressures these corpuscles are given off from a hot wire or from the carbon filament of an incandescent lamp. He has also demonstrated that this property of emitting

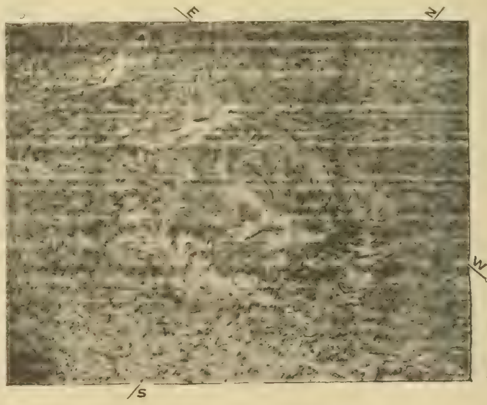

FIG. 3.—Same Region of the Sun, showing the Hydrogen (Hα) Flocculi. 1908, April 30, 5h. 06m. p.m. P.S.T.

corpuscles at high temperature is common to carbon and to metals, whether in the solid or in the vaporous condition. Thus we have warrant for the belief that the sun, composed of just such elements as constitute the earth, must emit great numbers of these corpuscles. As Thomson has estimated that the rate of emission of a carbon filament at its highest point of incandescence may amount to a current equal to several amperes per square centimetre of surface, we can hardly be mistaken in assuming the existence of still more powerful currents in the sun. The emission of negatively charged particles implies the emission of positively charged particles, but in laboratory experiments, because of unequal rates of diffusion or other causes, charges of one sign are always found to be in excess. We thus have reason to believe that powerful magnetic fields may result from the revolution of these particles in the solar vortices.

In seeking a means of detecting such fields, let us first recall Faraday's discovery of the effect of magnetism on light, made at the Royal Institution in 1846. This discovery relates to the rotation of the plane of polarisation of light when passed through a plate of dense glass in a strong magnetic field. Although Faraday, in what was said to be his last experiment, endeavoured to detect the effect of magnetism on the lines of the spectrum, he failed because the apparatus then available was not sufficiently powerful. In 1896 Prof. Zeeman examined with a large spectroscope the two yellow lines emitted by sodium vapour in a flame between the poles of a powerful magnet. Observing in the direction of the lines of force, he saw that the sodium lines widened when the magnet was excited. Subsequently, with more powerful apparatus, he found that a single line, when observed under the above conditions, is split into two components by a magnetic field. The distance between the two components is a measure of the strength of the field; but the most characteristic quality of these double lines, which distinguishes them from double lines produced by any other known means, is the fact that the light of the two components is circularly polarised in opposite directions. If, then, we encounter a double line in the spectrum of any substance, and suspect it to be due to a magnetic field, we must apply the test for circular polarisation.

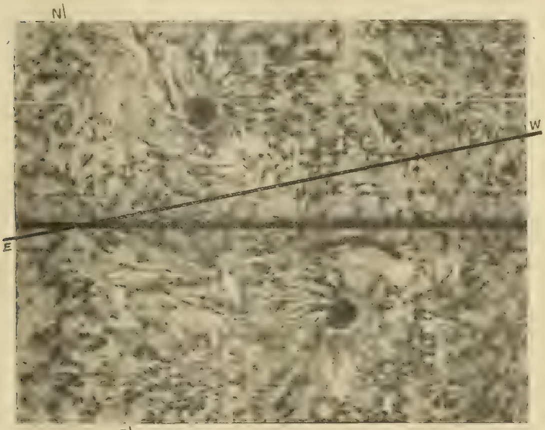

FIG. 4.—Sun-spots and Hydrogen Flocculi, showing Right- and Left-handed Vortices. 1908, October 7, 7h. 02m. a.m. P.S.T.

The simplest means of testing for circularly polarised light is to transform it into plane polarised light by passing it through a quarter-wave plate or a Fresnel rhomb. In the case of a Zeeman doublet, we would then have issuing from the rhomb the light of the two components, polarised in planes at right angles to one another. A Nicol prism, standing at a certain angle, will transmit one of these plane polarised beams and cut off the other. Turning the Nicol through 90° will cause the component previously cut off to be transmitted, and the other to be stopped.

Consider a sun-spot at the centre of the solar disc, and suppose it to be produced by a vortex, the axis of which lies on the line passing from the eye of the observer through the spot to the centre of the sun. In these circumstances, if a strong magnetic field is produced by the vortex, the spectral lines due to vapours lying within this field should be widened or transformed into doublets. Moreover, the light of the components of these doublets should be circularly polarised in opposite directions. This would be true if the spot vapours were emitting bright lines, identical in character with those emitted by a radiating vapour between the poles of a magnet. The experiments of Zeeman, Cotton, König, and others, show, however, that dark lines, produced by the absorption of the spot vapours, should behave precisely in the same way as bright lines.

The spectrum of a sun-spot was observed for the first time by Lockyer in 1866. He found that many of the lines of the solar spectrum were widened where they crossed the spot, and the observation of these widened lines has been carried on systematically by many observers ever since. Conspicuous among these observers was Young, whose last observations were made with a powerful grating spectroscope attached to the 23-inch Princeton refractor. This instrument showed that some of the spot lines are close doublets. Dr. Walter M. Mitchell, who at first worked in conjunction with Prof. Young, and later by himself, gave special attention to these double lines, which he found to be particularly numerous at the red end of the spectrum. He called them "reversals," and the existing evidence favoured the view that they were produced by the radiation of a hotter layer of vapours overlying the spot, which would give rise to a narrow bright line at the centre of the widened dark line. True reversals of this kind actually seem to occur in the case of H and K and other lines in the spot spectrum, and it was therefore natural that Mitchell should attribute the similar phenomena of the spot doublets to a similar cause. It was generally supposed that the widening of the dark lines was due to the increased density of the spot vapours. The diverse character of the lines in the sun-spot spectrum is well illustrated by this drawing, which is due to Mitchell. In addition to the ordinary widened and "reversed" lines we find cases where a dark central line is accompanied by wings, others in which lines are thinned or completely obliterated, &c.

(*To be continued.*)

RECENT AGRICULTURAL PUBLICATIONS FROM THE WEST INDIES.

THE imperial Department of Agriculture for the West Indies issue three periodical publications:—(1) the *West Indian Bulletin*, a quarterly scientific journal containing papers or reports by members of the scientific staff, or papers read at agricultural conferences; (2) the *Agricultural News*, a fortnightly paper, published at one penny only, containing short articles in popular language on subjects of importance to planters; (3) a series of bulletins, each containing detailed information on some special subject. In addition, reports are issued on the work done at the different experiment stations on some of the islands, and the Department of Agriculture for Jamaica issues a separate bulletin of its own.

During the present year the last number of vol. ix. of the *West Indian Bulletin* and the first of vol. x. have been published. The timbers of Jamaica are described at some length by Mr. Harris, no less than 108 varieties being dealt with, and a similar article describes 176 trees found in Dominica. Dr. Watts and Mr. Tempany discuss the soils of Nevis in a very luminous paper. Mr. W. Biffen writes on soil inoculation, and describes a number of experiments made in various parts of the West Indies with Prof. Bottomley's cultures. No increase in crop was produced, excepting only in two cases; this result is, of course, quite in accordance with careful trials made elsewhere.

The *Agricultural News* is altogether distinct in type from any other agricultural paper. It consists almost entirely of scientific articles, some original and some quoted from other sources, but all bearing on the problems of West Indian agriculture. With a body of scientific men like the staff of the West Indian departments there is probably no great difficulty in getting "copy," but it is interesting and significant that the "news" should be appreciated by the planters. An interesting economic problem is raised in one of the issues. The West Indies are, of course, almost purely agricultural, yet quantities of food-stuffs are imported. In the Leeward Islands, for instance, the total value of all imports for 1906–7 was 407,251*l.*, of which 151,260*l.* was for food, viz. 46,751*l.* for wheat flour, 13,593*l.* for corn meal, 12,657*l.* for salt pork, hams, and bacon, 9127*l.* for bread-stuffs, 8537*l.* for rice, and 991*l.* for peas and beans. No doubt it is economically sound for these islands to grow for export such staple products as sugar, cacao, cotton, limes, bananas, and to import the above food-stuffs; but in many of the West Indian islands there are men unemployed and land uncultivated; moreover, crops like cotton require some sort of rotation. Why could not some scheme be evolved for raising on the spot the bulk of this imported produce? The question is discussed in a broad, masterly way in an interesting and informing article.

Of the recent pamphlets dealing with special subjects that have reached us, three relate to the sugar-cane. Experiments have been in progress some years in Antigua and St. Kitts to ascertain those varieties of sugar-cane which are likely to give improved yields of sugar, and, at the same time, to show increased resistance to disease. In the manurial trials it is found that sulphate of ammonia or nitrate of soda alone, *i.e.* without potash or phosphate, is the most profitable form of manure for ratoon canes. Sulphate of ammonia proved more useful than nitrate of soda, probably due to its being less liable to loss by leaching. Potash and phosphate still further increase the yield, but not to a sufficient extent to pay for the additional fertiliser. Dried blood did not prove remunerative. Very full details are published in a separate report. Experiments on similar lines are made at Barbadoes; the results are very similar, but the increased yield obtained by the use of potassic manures was profitable.

Jamaica has its own Department of Agriculture and publishes its own bulletin. The new series began in April of this year under the editorship of the director, Mr. H. H. Cousins, and it is well got up and illustrated with very good photographs. Mr. Cousins contributes articles in his usual lucid style on rum, cassava, starch, mangoes, and other important local industries. Mr. Ashby discusses the yeasts of the rum distilleries, and in another article the bacteria of the soil, and Mr. Harris describes the timbers of Jamaica.

THE QUINQUECENTENARY OF THE UNIVERSITY OF LEIPZIG.

THIS year, the year of anniversary celebrations, has been an *annus mirabilis* for other countries than our own. In Germany Leipzig has been commemorating her five-hundredth birthday, and Prof. Wundt, her official historiographer, had a crowded and distinguished audience before him in the theatre at Leipzig, an assemblage including the King of Saxony, the Royal princes, and many learned delegates drawn from all four quarters of the globe; but some notice must be taken of the previous history in order to understand and to preface Prof. Wundt's enthusiastic and interesting discourse.

Charles IV., the first German King of Bohemia, in 1349 established at Prague the first German university. About half a century later, and in the throes of the Great Schism, whilst Wenceslaus was still occupying the Imperial throne, there was a great national and religious revolt in all the Slav domains of the Holy Roman Empire, and in the course of this upheaval the University of Prague was nationalised by the Cechs. Then, in 1409, a small band of German teachers and students left Prague, turned their faces northwards, and founded a new home at Leipzig. Prof. Wundt's address shows how fully he realises that the spirit of those first free emigrants was perpetuated in the great school they established. For in this her voluntary uprising, Leipzig is unique among the universities of Germany; her existence might be confirmed by the princes and electors, and she might acknowledge many benefactions from on high, but she was ever independent of both city and Sovereign. Yet this independence, this tradition of liberty, was sterilising; it rested on an essential immutability; until 1830, when the University had to commit her own suicide—but was spared the public executioner—and became a State institution, she remained scholastic, manacled with fetters of an age outworn.

Prof. Wundt thinks that the present age may witness a change, as at those two epochs when humanism and science forced a reluctant way in. As Leibniz said, "The past has ever been fulfilled by the future." "Wherever we look," says Prof. Wundt, "we see the force of new needs impelling us far beyond the original objects of the universities. The universities arose out of the bosom of the Church. The State was concerned with conserving a class of learned clerics, and thus availed herself of them as schools for the making of a learned officialdom; and thus the State cut herself free from the Church in the settling of the aims of the universities. But nowadays a third power is associated with the State, and is presenting an ever-increasing tale of demands, viz. the community. Society henceforth needs the State as a means of attaining its ends, just as the Church once similarly required the resources of the State." And the modern university will present a more motley and less secluded appearance; it will have to deal with the claims of women to a university education, to admit technical high schools and pupils from *Realgymnasien* to an equality with its original *alumni*, and to extend and expand to suit the manysidedness of modern life. Leipzig, very late in the day, at last had to succumb in the fight against humanism, and had to allow the newer teaching gradually to supersede scholastics. So, too, the University had to approve natural science and the linking of research to scholarship; but the present conflict is not "as of old, a struggle between irreconcilables, of whom only one may win; rather, the task of combining the ideal of the future with the whilom new ideal of culture."

The early centuries of the University are, on the whole, undistinguished. Not even the Reformation transformed it essentially. After the model of Paris, the University was divided into four "nations," each under its dean, the Meiszners, the Saxons, the Bavarians, and the Poles; but all these ancient differences have been swept away; this only remains, that, at every annual election, the statutes of 1554 are entrusted to the new officer, and the benevolent funds for poor students still subsist. Also every professor has, like the mediæval *magister*, a *famulus*! In 1543 Maurice, the great Elector of Saxony, gave the University the old Dominican monastery of St. Paul, which was itself built on the foundations of one of the three castles erected in 1217 to cow the city. There were, as is usual in the story of university life, many town and gown riots, perhaps, as the professor suggests, survivals of the old Bohemian spirit of liberty. The University was a close corporation, rigidly scholastic, with only one faculty, theology, up to which all other branches of knowledge necessarily led; and then, too, "it was the fate of the German university that its development should have begun at a period of the decay of learning." When the sleep of the other universities was being broken by dawning humanism, Leipzig resisted longer than any other; and the University of Leipzig was regarded as an almshouse for irremovable *magistri*, and for some time, during the horrors of the Thirty Years' War, young children were matriculated in large numbers so as to secure them some legal immunity; there were only a few dozen students, so that the almshouse became a nursery as well.

In the eighteenth century the great struggle was, first, to secure admission of the German language for formal purposes, and, secondly, to ally research with study. In 1710 Augustus the Strong granted an observatory, very much in opposition to the University authorities, who, like true scholastics, deemed all teaching should be theoretical. "If a professor made chemical or physical experiments, such were utterly outside his profession. . . . Even an anatomical lecturer did something very supererogatory if, even once a term, he exhibited the position of the entrails to his class. . . ." But the *Universitas Scholastica*—not yet the actual *universitas litterarum*—even in its theoretical teaching, had to be permeated by the modern spirit, and to admit, as subjects, architecture, military science, and so forth, and even, in the *universality* of its strivings, quite technical matters, afterwards more fitly relegated to the polytechnics. Later, at the beginning of the last century, when the University of Berlin was inaugurated, Humboldt's words mark the great change. "Research and teaching must coexist, each in its place, and teacher and pupil must be partners. . . . The strength of the elder mind, more practised, but weaker and more cramped, must act in unison with the spirit of youth, less reliable but more enterprising. With this process of exchange the State must not meddle . . . it must supply the wherewithal and select the right men." So too Schleiermacher. "The teacher must be wholly free and gather round himself a seminary of fellow-seekers, thus constituting scientific research as a means to something greater, namely, a school of character." But Prof. Wundt sees two sorts of dangers ahead. First, that politics may enter into the scholastic world and affect the choice of competent instructors, and, secondly, that university teachers, though they be civil servants, may not recognise the essential differences between them and ordinary State officials, *e.g.* that such rules as promotion by seniority cannot apply to them. Instances of the former peril at Leipzig have been the enforced resignations of Mommsen, Otto Jahn, and Moritz Haupt.

One great reform the University of Leipzig has accomplished. The old foundation, professing to be universal, was little more than an ultra-conservative high-school for Saxony, in which great men found it hard to breathe freely; thus Leibniz was forced outside. But the modern State institution is at least German, and not "particularistic." The teachers are drawn from every part of Germany and German-speaking Austria, and the University, if not international, as in olden time it professed to be, is a national school of a united nation.

The early attendances at the University are difficult to gauge. The practice of matriculating children, of not including teachers and students who came in *extra ordinem* (*i.e.* not as members of the corporation), the irregularity of attendance (varying for the terms; in the winter the students mostly went home), and the inadequacy and vagueness of the old lists, all these causes make any accurate computation impossible. The average is from 350 to 450, rising between 1609 and 1629 to 800, sinking in 1634 and 1645 to less than 100. This severe fall more or less corresponds with the Thirty Years' War. Another noticeable drop (1520–40) may tentatively be accounted for by the superior attractiveness of Wittenberg (where Luther was staying) and the troubles of the Reformation. After the establishment of the present Empire the numbers rose in ten years from 700 to 2000, and in 1908 stood at more than 2300.

Prof. Wundt's long address, which is published by Mr. W. Engelmann, of Leipzig, leaves something to be desired. He gives few details as to the modern extensions of the University, of its new buildings, of the student associations, and in his estimate of the coming problems he expresses himself indecisively, perhaps discreetly. It would, too, have been interesting to be able to correlate better the progress of German history and the developments of this ancient corporation; but perhaps there is little more to be said, for, until the revolutionising change of 1830, there was little alteration. But a university with so high a claim to veneration for antiquity, so great a repute for modern achievement, could hardly have found a more distinguished commemorator.

INTERNATIONAL CONGRESS ON PURE FOODS AND ALIMENTARY SUBSTANCES.

THE second International Congress on Pure Foods and Alimentary Substances, held in Paris on October 17–24, will be memorable as having brought together more than 2000 delegates and members from all parts of the world. The actual number of countries represented was twenty-eight, and these included States so remote as China, Japan, Uruguay, Mexico, and Brazil. All the European States, as well as America and the British colonies, were fully represented.

The British delegation was a representative one, and included delegates from various learned societies and other associations interested in a pure food supply. The meetings were held in the College of Medicine, Paris, which was kindly placed at the disposal of the congress by the faculty, and the various class-rooms, together with the commodious amphitheatre, were taxed to their full capacity to accommodate all those present. Indeed, on the official opening day, October 18, it was quite impossible to find room for half the members who desired to hear the speeches. The address of welcome was given by M. Ruau, Minister of Agriculture of France, who dwelt on the great work being carried on by the White Cross Society of Geneva, under the auspices of which the second International Food Congress was held. The White Cross Society was called into existence as a companion organisation to the Red Cross Society, the efforts of which have proved so successful in mitigating the horrors of war. It is the mission of the White Cross Society to try to ameliorate the evils of our modern social system, and in no respect is this more needful than in connection with the food supply.

Prof. Bordas, chief of the customs laboratories of France, as president of the congress, reminded the members present that the first congress, which was held at Geneva, had defined what should be the constitution of pure food, primary products in connection with drugs, and various alimentary substances, all of which had been set forth in the *Comptes rendus*. It would be the business of that congress to continue these definitions and determine precisely what operations should be allowable in the handling of such substances. When that was complete it would then be necessary to try to unify analytical methods or show exactly what relation one analytical process bore to another, so that the results attained would be comparable equally. When such a basis of comparison was arrived at, it would then be easy to place the whole department of the supply of food and alimentary substances under legal control in all countries.

The work of the congress was divided up into various sections, the duty of which it was to come to definite conclusions in connection with various substances and report such decisions to the section of hygiene, which formed a kind of court for reviewing the work done in other departments.

The sections included:—(1) drinks and beverages, wines, liqueurs, cider, perry, beer, vinegar; (2) bread, flour, pastry; (3) confectionery, honey, sugar, sugar preparations, cocoa, chocolate; (4) spices, tea, coffee, mustard, salt; (5) dairying, milk, cream, condensed milk, butter, cheese, eggs; (6) charcuterie, the meat industry, edible fats, preserved provisions, preserved fruits and vegetables, sausages; (7) primary products in connection with drugs, essential oils, chemical products; (8) medicinal and other mineral waters, ice.

The consideration of such a formidable list necessarily meant continuous hard work, and it is only fair to say that the attendance at the sections was everything that could be desired, and the department of hygiene was crowded from first to last, it being estimated that in it alone the average attendance exceeded 500.

It would not be desirable to attempt to review the various discussions in detail, suffice it to say that the definitions were completed, and, as the president announced, will be published as soon as possible in French, German, and English. It may be of interest, however, to refer to some of the more notable decisions.

Bread was declared to be the product resulting from the baking of dough made from pure wheat flour, with the addition of yeast, water, and salt. Any other product meant as a substitute for bread should not bear the name, and its composition should be declared at the time of sale. It was subsequently declared that the addition of baking powder, bicarbonate of soda, and tartaric acid were quite permissible and regular operations. Alum was entirely prohibited.

Coffee was clearly defined as being only worthy of that name when derived from coffee berries and when free from any foreign mixture, such as chicory or any other substance. Cocoa, on the other hand, was not so easily defined. Long discussions on the composition of this product took place in the section, and it was agreed that it would be better to refer the matter to an international commission of experts. The main question was as to whether the addition of alkali to cocoa was justifiable or not. The large manufacturers said that it was unnecessary, but the small makers, who were in the majority, held to the view that not only was it allowable, but it was necessary, so as to enable them to produce a cheaper cocoa than that sold by the large makers, and at a cheaper price. They asserted that the buyers for whom they catered belonged to a class which could not afford the high prices asked by large manufacturers. To prohibit the use of alkali meant the practical extinction of the small makers and the creation of a vast monopoly in the hands of a few. The discussions on the subject in the hygienic section were prolonged and sometimes very heated, but in the final issue it was agreed that 2 per cent. of alkali should be allowed. An international commission will consider the whole matter, as it appears that cheap cocoas are not only sophisticated with alkalis, but additions, which are simply adulterations, are common. It is strange to hear, for example, that one manufacturer uses paraffin wax in his produce!

If the discussions on cocoa were animated, so also were those on butter. At the Geneva congress there seemed to be a feeling that the definition of pure butter was a political rather than a hygienic question, and the voting seemed to be between the fresh butter and the salt butter makers. Owing to the greater attendance at the Paris congress there was a greater body of opinion, hence the discussions were more prolonged, and, for that matter, more interesting. The first question was as to the empirical standard of 16 per cent. of water, which, it was declared, was too low for general purposes. It was finally raised to 18 per cent.

The next question was in connection with the use of preservatives, and it was shown that it was not possible to conduct an export butter trade over any great distance without the addition of some boron preservative. This addition was allowed, and classed as a regular operation (*opération régulière*), which means that it is now considered as necessary in the making of some kinds of butter as is the addition of salt, and need not, therefore, be declared. Colourings for food, confections, and liquids came in for considerable attention, and it was found impossible to resist the argument that the sale of many alimentary products depended to a large extent on their appearance, and the use of harmless colours was therefore permitted. Twenty anilines were specifically mentioned as being innocuous, and they embrace every shade used for food purposes.

The discussion of ice elicited quite a display of feeling, and an acceptable definition was not arrived at without some difficulty. It was finally agreed, however, that there were two kinds of ice, namely, manufactured and artificial. The manufactured article should be produced only from sterilised or town's water. Natural ice could only be admitted for addition to, or for bringing in contact with, foods, when gathered from lakes, rivers, or canals under proper sanitary control.

Medicinal mineral waters did not emerge from the discussions well. It appears that there is quite an industry in manufacturing these and sending them out into the world under apparently genuine labels, and the "source naturelle," or natural spring, is too often the town supply of water to which a small percentage of alkaline salts is added! To control fraud such as this is difficult, and nothing short of making it a penal offence would be of much use.

In connection with drugs, a long discussion ensued upon the presentation of a brochure by Mr. C. Umney, in which he set forth the desirability of instituting international control of specific substances, and it is not unlikely that, as the matter is of such world-wide importance, an international commission may be appointed to study the whole question in detail.

These references will show that the work accomplished was very great, for it must be borne in mind that each subject on the programme had to be discussed and resolutions arrived at. The manifest pains which were taken to arrive at correct definitions impressed those present.

The feature of this congress was earnestness and a strong desire to coordinate practice with hygienic requirements, and when the *Comptes rendus* are published it will be seen how very thoroughly the work was carried out.

It has not yet been decided where the next congress will be held. The choice lies between Rome, Brussels, and London, but a decision cannot be arrived at until later.

It may be mentioned that much hospitality was shown to the visitors. The city of Paris gave a reception at the Hôtel de Ville, and the Minister of Finance at the Ministry. Various visits to notable food factories, such as that of Messrs. Potin and the chocolate factory of Messrs. Menier, were arranged. Parties also visited the brewery of Messrs. Karcher, the Gobelins lace factory, and Sèvres porcelain works. Amongst those who dispensed lavish private hospitality were Madame and M. Paul Bolo, to whose initiative the White Cross Society of Geneva owes its origin, and whose generosity enabled it to call the first congress together at Geneva last year.

LOUDON M. DOUGLAS.

EDUCATION AT THE BRITISH ASSOCIATION.

THERE can be no gainsaying the fact that education received quite its fair share of attention at Winnipeg this year. Readers of NATURE have already had an opportunity of considering the words of warning in Sir J. J. Thomson's presidential address to the association on the excessive competition for scholarships now confronting the student of every grade in England, and on the evils which the consequent premature specialisation brings in its train—the dulled enthusiasm for knowledge and the inadequate literary culture. In the physiological section, also, Prof. E. H. Starling shed a fresh light on the meaning of the word by applying to it the conception of man as the last result of an evolutionary process.

In the Educational Science Section itself, Dr. Gray's presidential address, printed in NATURE of October 7, was concerned with "The Educational Factors of Imperialism," and in the course of it he developed an attack on the "grand old fortifying classical curriculum" with a boldness remarkable in one who is at the head of an English public school, and, as Prof. Armstrong said, is one of the most successful teachers of Greek we have.

Manitoba lags behind its younger sisters, Alberta and Saskatchewan, in that elementary education is not by law compulsory, and the pronouncement made by Dr. Kimmins, one of the vice-presidents of the section, in favour of compulsion probably attracted as much outside attention as any utterance in the section. For two days the blackboards outside the *Free Press* office, which appear to constitute the principal reading of many inhabitants of Winnipeg, informed the constant crowd that "Dr. Kimmins had expressed astonishment that education was not compulsory in Manitoba."

To the regular attendants of the section, however, the contributions of the two American vice-presidents, Prof. Hugo Münsterberg and Principal J. W. Robertson, were the outstanding features of the meeting.

Prof. Münsterberg spoke at some length on the last day of the meeting, and to a good audience, on the relations of education and experimental psychology. He began by drawing a striking contrast between the attitude of teachers here and in America towards psychology. In England psychology is neglected, and the teacher is like the farmer who turns his back on chemistry—his methods remain clumsy and old-fashioned. In America, on the other hand, the value of the subject is overestimated, and the teacher commits the grave mistake of subordinating the whole of his art to scientific psychology; but a science gives us the means, not the aim. The psychologist regards the inner life as the physicist regards the outer. He shows us how the pupil's mind imitates; he cannot tell us what is worthy of imitation. It is to ethics we must look to give us our goal before we apply to psychology for the means to reach it.

Again, the psychologist is seeking the relation of cause and effect, and for that he must analyse personality. The child's mind is to him a combination of elements, as the physical thing is a combination of atoms; and so psychological truth differs from the truth of life. The child, for the educator, is a unity to be understood, not a bundle of conditions to be described. The teacher must beware of any tendency to inhibit those emotional responses of personality to personality. Tact and sympathy and love and interest are the things which matter in educating the young.

Yet, if its dangers are well understood, the knowledge of experimental psychology ought to be at the disposal of the teacher just as experimental physics ought to be familiar to the engineer. Psychology in the past has been a strictly theoretical science, having little or no connection with practical needs; but in the last decade the connections have been made; the practical problems have been studied in the laboratory in the light of psychological facts. There is a body of psychology applied to education which the teacher can use with safety.

Of this applied psychology Prof. Münsterberg gave several interesting examples drawn from his own laboratory practice. He told us how, by experimenting with nonsense material, the effect upon remembering of repetition, of a lengthened time interval between hearing and recollecting, of reading as against writing and saying, had all been studied. He showed that the learning process is not coterminous with the process of taking in, but that a period of rest, in which the impressions settle, as it were, and organise themselves with the previous content of the mind, is requisite. He laid it down that piecemeal learning is an illusion, and that, within certain ascertainable limits, the larger the group of impressions the better they are remembered. Finally, he pointed out that it is possible to relate individuals to certain definite types, as, for instance, those whose memory is visual and those in whom it is acoustical, and indicated the relevancy of the facts, not only to the educational process, but also to the selection of a calling for the child, since every calling demands certain characteristic traits.

Dr. J. W. Robertson, the second American vice-president of the section, is the first principal of MacDonald College, which has been established at St. Anne de Bellevue, a few miles from Montreal, at the west end of Orleans Island, through the generosity of Sir William MacDonald. The college buildings alone cost nearly half a million dollars, and, standing as they do immediately north and south of the two great trunk lines of Canada, which at this point run side by side, cannot fail to attract the attention of every traveller to the western prairies. They are, indeed, a worthy monument of their founder and of the genius of the man who inspired him to build this great house of education.

Dr. Robertson addressed the section on the history and aims of the college. He described the college as an effort for the betterment of rural life in Canada. We are face to face here, he said in effect, with problems which are peculiar to ourselves—problems due to our youth, to our vast stretch of territory, to the great potential value of our resources, to the broad stream of foreign blood which is pouring into our citizenship. Wealth may come, is coming with great rapidity, but real progress and stability in national life keep side by side with progress in intelligent labour, and that depends upon education.

MacDonald College has grown out of a desire to help the rural population to build up the country and to make the most of it and of themselves. The rural school must be adjusted to the needs of the people; it must have a bearing on the life interests, the occupations, and the opportunities of the locality. From the course of study in many rural schools to-day you would not suppose that the fathers had any concern with the soil, with crops or animals. At MacDonald College we instruct and train for the three fundamental mothering occupations which nurture the race, first, farming, whereby man becomes a partner with the Almighty, and through cooperation with nature obtains food and shelter and clothing; secondly, home-making; thirdly, the teaching of the children. The training of leaders for these three fields of endeavour is being carried on in close correlation. Until recently, the teachers and the agricultural students were segregated for training, and the courses of study of neither class contained much which identified education with the activities of the home. Now the home, the farm and the school are finding common ground, to the great advantage of all three.

We are all part of nature; our lives, the transient and the eternal, are sustained by natural processes under natural laws. The study of nature, then, must lie at the root of all education. Nature-study, too, deals with the facts and principles on which a systematic study of agriculture can be founded; and next to nature-study comes manual training, which is similarly a basis for technical and industrial education. Every boy and girl should go through a course of manual training. Think of its value in the making of character. How many men there are who need the stimulus of others' approval to keep them in the right way. Here is something which the boy can assess for himself; he does not need the teacher's blue pencil to tell him whether his woodwork is right or wrong. He judges it for himself and judges himself—"that is not so good as I can make it." See, too, how it teaches the lesson of all lessons the most important, the lesson of consequences—"the joint will not fit because I did that wrong."

If the people starve the schools and colleges, the schools and colleges will retaliate by letting the people starve mentally, then morally, and in a measure materially too. "Once I saw a field of which the owner said, 'I let the crop take care of itself, and in three years there were only two small heads of wheat among the weeds.' For the bare maintenance of human life there is need for practical education." It is hopeless in a bald summary to attempt to recapture the enthusiasm, the intimacy, and the individuality of Dr. Robertson's address. Those who heard him will not soon forget the experience.

A useful discussion upon moral education was opened by Prof. L. P. Jacks. The demand for moral training has been reinforced by the growth of the imperial idea, which is awakening the national conscience and confronting the individual citizen with enlarged responsibilities. Morality cannot be made one among a number of set subjects; what is needed is the idea of an "end" under which the purposes of life may be coordinated. Loyalty to the State is such a principle. Neither can the virtues be taught on a fixed pattern; the attempt to do so leads inevitably to reaction against the idea of morality. The teacher must be content to put the truths of their environment before young minds in such a light that the facts themselves, when so explained, become incentives to morality. Mr. Hugh Richardson followed with a plea for a scientific investigation of methods and results. He pointed out how extraordinarily little evidence there is as to what results have been produced, still less is there any evidence as to which processes have produced which results. The speakers following agreed with Prof. Jacks that direct moral training was of little worth.

Prof. Münsterberg, however, thought that teachers should keep the ethical "end" always before them. There are tendencies in education to-day which are bringing weakness of character in their train. It is not wholly good that the methods of the kindergarten should be allowed to creep up the primary school and the elective systems of the high school to descend to it. The problem of education to-day is the cultivation of the power of voluntary attention. The child is naturally attracted by what is loud and bright and shining. If everything is made easy and pleasant for him as a child, as a man he will always remain in thraldom to the momentarily attractive; he will let things slide. The good life is neither easy nor pleasant; the things that matter are not loud and bright and shining.

A discussion which attracted much local interest was initiated by Dean Wesbrook, of Wisconsin, on university education, in which Mr. W. A. McIntyre, principal of the

Provincial High School and Normal School, and Principal Murray, of the University of Saskatchewan, took part. The University of Manitoba at present is hardly more than a group of science faculties supplementary to the arts courses provided in the affiliated denominational colleges. Alberta and Saskatchewan are laying the foundations of what will one day be strong State universities, and Dean Wesbrook did not disguise his opinion that this was the right course to pursue. In the course of the discussion Mr. C. R. Mann, secretary of Section L of the American Association for the Advancement of Science, spoke of the direct influence which the needs of the community at large must have upon the work of a State university.

Mr. W. M. Heller, a vice-president of the section, opened a symposium on practical work in schools with a paper on the report of the committee on practical studies, which was presented at Dublin last year. Dr. Kimmins contributed a paper on the London trade schools; Miss Lilian Clarke an address, illustrated with the lantern, on scientific nature-study in secondary schools; and Mr. W. Hewitt read a thoughtful paper on practical work in continuation schools and evening classes. Mr. Walter Sargent, of Chicago University, claimed a place in the primary-school curriculum for manual training for the purposes of industrial education. In many localities in America 80 per cent. of the children leave before the end of the primary course. These children drift into unskilled occupations, and spend often two or more years in employment which awakens no industrial interest and offers no vocational outlook. For these children an optional course should be provided, planned definitely to promote industrial efficiency. Those who argue that this would abridge the period of cultural education, already too short, were reminded that no sharp line can be drawn between cultural and industrial education. "Most of the activities which have raised men from savagery involved a utilitarian test of their result. Utilitarian is a word the meaning of which becomes more inclusive with advancing civilisation."

In the discussion on the teaching of geography Profs. Dodge, Johnston and Brigham, Mr. Chisholm, and Dr. C. H. Leete took part. To one trained in geography on the old topographical method, or want of method, who is watching its gradual displacement by the more scientific regional geography, it was novel to hear that in the high schools of the United States there is practically no serious study of regional geography. The physiographical text-books in use in America are admittedly much in advance of our own, but the advance appears to have been at the expense of the student, who, after his fourteenth year, is condemned to the study of classifications principally of land forms with reference to their origin rather than to their effect upon human and animal life. Happily, there are signs of change. Prof. Brigham's account of how he was driven back upon topography pure and simple in his endeavours to aid a young student of his own kin who was floundering in a text-book on physiography (very likely his own book!) amused his English hearers, and, it may be hoped, was not lost upon some of his brother professors across the water.

The closing discussion, on education as a preparation for Canadian life, was opened by the president, who proposes to test his theories on a farm for English public-school boys which he is establishing in the neighbourhood of Calgary. He was followed by Mr. S. E. Lang with an account of high-school work in agriculture. Miss Benson described the household science course at Toronto University, and Miss Oakley gave an account of the similar course at King's College, London. Mr. Eggar spoke of the value of school games. If the principle that it was better to lose a game than to win it unfairly were true, then school games had a grand moral as well as a physical effect.

An account of the proceedings would be incomplete without some mention of the collection of brush drawings by pupils of the Village Hall School, Weybridge, which Mr. T. S. Marvin's pertinacity had brought intact through the Canadian customs. This interesting exhibit had been designed to help children in Canadian schools to realise the conditions of child life in England. There were series of brush drawings illustrating rooms in English houses, methods of going to school, bric-à-brac, portraits of the artists, and so on. Nature-study was illustrated by sketches of plants characteristic of the different months, and studies of the seasonal growth and decay of common wild flowers. The purpose of the drawings was excellent, and was carried out in a charming fashion. The nature-study work reached a high standard of accuracy, and almost all the drawings showed great artistic merit. It is pleasant to think that the collection will remain in Manitoba to pay a double debt—as a token to the educators of the province of our gratitude for their efforts on our behalf and as a reminder to the children of their child cousins on the other side of the sea.

CONFERENCE OF DELEGATES OF THE CORRESPONDING SOCIETIES, BRITISH ASSOCIATION.

IF the annual conference of delegates of the local societies in correspondence with the British Association had been held at Winnipeg, it is not likely that many societies in this country could have sent representatives. It was consequently decided to hold an autumn conference in London, as was done after the South African meeting four years ago. Accordingly, a conference was held on Monday and Tuesday, October 25 and 26, in the rooms of the Geological Society at Burlington House, under the chairmanship of Prof. A. C. Haddon, F.R.S. As many of the delegates from the provinces arrived in London on the preceding Saturday, an official visit to Kew Gardens was made on Sunday afternoon, when the delegates were received by Lieut.-Colonel Prain, F.R.S., and Dr. O. Stapf.

The conference was opened on Monday morning by an extemporaneous address from the chair, in which Dr. Haddon urged the local societies to carry out observational work of an original character. Regional surveys might well be undertaken. Intensive work in the special areas within range of the activities of the respective societies would ultimately lead to a close knowledge of the whole country. Dr. H. R. Mill's detailed study of a district in the south-east of England was naturally held up as a model; and reference was also made to the excellent work of Prof. A. W. Clayden on the origin of the scenery of Devonshire, and to that of Prof. W. W. Watts on Charnwood Forest. Turning to our rivers as a suitable subject for local study, Dr. Haddon referred to the work of Prof. W. M. Davis, remarking, incidentally, that it was rather strange an American should have to teach us how to read the story of our own streams. With regard to zoology, the chairman explained that when he worked under F. M. Balfour he was an enthusiastic embryologist. Notwithstanding the advance of special work in the higher departments, there was still ample room for the amateur in zoology. Anthropometry, again, was a subject that might well be taken up by the local societies.

A paper on national anthropometry was read by Mr. J. Gray, the secretary of the anthropometric committee of the British Association. He explained the methods of measurement, and exhibited on the screen the excellent figures prepared by the late Prof. Cunningham to define the exact points of reference on the living subject, from which measurements should be taken. The instruments used are inexpensive and their use not difficult, so that, in the absence of a national system of anthropometry by a Government department, the natural history societies in each county might well undertake the work. A demonstration was given, and many of the delegates were measured. Attention was also directed to the various means now used to estimate quantitatively certain mental faculties.

A prolonged discussion was initiated by Prof. Meldola, F.R.S., who desired to elicit from the delegates their opinion as to the expediency of establishing a fund, with Government aid or otherwise, for the purpose of assisting scientific societies in the publication of original work. Many societies were crippled by insufficient means, and it was believed that much good work in the country remained unpublished, or, if published, was insufficiently illustrated, whilst in many cases the proportion of income expended on publications was so great as to hinder the activity of the societies in other directions.

Sir Alexander Pedler, F.R.S., explained how the British Science Guild had sought to relieve the scientific societies by endeavouring to obtain a reduction in the rate of postage of their publications, but he much regretted that the Postmaster-General, though sympathetic, could not see his way to grant such relief. Some of the delegates suggested a renewal of the application, but it seemed unlikely that this would be successful. The general question of founding a publication fund was discussed by representatives of many scientific societies, including the Chemical, the Royal Astronomical, the Zoological, the Entomological, the Royal Anthropological Institute, and the Institution of Mining Engineers.

In a paper on the financial position of our local societies, Mr. John Hopkinson sketched the history of the Hertfordshire Natural History Society, and showed how a society which had always struggled with a small income had yet managed to publish excellent original work.

Although the opinion of the conference was generally favourable to the formation of a publication fund, a few speakers expressed the opinion that it would be inexpedient to take any step which might tend to increase the publications of local societies, inasmuch as the mass of such literature was already embarrassing to the bibliographer.

On the afternoons of Monday and Tuesday the delegates visited, under scientific guidance, the Natural History Museum and the Zoological Gardens.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—An election to the Clerk-Maxwell scholarship will take place at the end of this term. Candidates are requested to send in their names to Sir J. J. Thomson on or before December 1.

Dr. G. H. F. Nuttall has been re-elected to the Quick professorship of biology. Mr. J. S. Gardiner has been elected to the professorship of zoology and comparative anatomy. Mr. E. O. Lewis has been appointed demonstrator of experimental psychology until Michaelmas, 1911; and Mr. D. G. Lillie has been elected to a Hutchinson research studentship for natural science.

Mr. H. F. Tiarks has supplemented Messrs. J. Henry Schröder and Co.'s gift of an endowment of a professorship of German by placing at the disposal of the University the sum of 5000*l.* for the endowment of one or more scholarships for the encouragement of the study of German in the University.

IT is announced in *Science* that Mr. Andrew Carnegie has subscribed 20,000*l.* to McGill University as a part of the general fund of 400,000*l.* which friends of the University are trying to raise.

THE Black Bear Press, Cambridge, has sent us a copy of the first issue of a new weekly magazine, the *Gownsman*, which is to be a record and comment of university life. The contents range over every department of university activity—academic, athletic, social—and the periodical should appeal to all Cambridge men, past and present. With this first issue is published, as a supplement, an excellently reproduced portrait of Sir Joseph Thomson, F.R.S. The price of the new publication is 2*d.* weekly.

THE annual meeting of the Association of Teachers in Technical Institutions will be held on November 6 at St. Bride Institute, Fleet Street, E.C. The chair will be taken at 3 p.m. by Mr. J. Wilson, who is the president of the association for the coming year. The report of the council will contain an abstract of the educational and professional work accomplished during the year. The educational work comprises the consideration of such questions as syllabuses in such subjects as applied mechanics and electrical engineering, the training of craftsmen, the preliminary training of technical students, and the Royal Commission on university and higher education in London.

IN his inaugural address, at the beginning of the present session, the president of Harvard University, Dr. A. Lawrence Lowell, discussed an ideal college training from three points of view. He considered the highest development of the individual student, the proper relation of the college to the professional school, and the relations of the students to one another. Each line of thought led him to the same conclusion. The best type of liberal education in our complex modern world aims at producing men who know a little of everything, and something well. The essence of a liberal education, said Dr. Lowell, consists in an attitude of mind, a familiarity with methods of thought, an ability to use information rather than a memory stocked with facts, however valuable such a storehouse may be. No method of ascertaining truth, and therefore no department of human thought, ought to be wholly a sealed book to an educated man. It has been truly said that few men are capable of learning a new subject after the period of youth has passed, and hence the graduate ought so to be equipped that he can grasp effectively any problem with which his duties or his interest may impel him to deal. In the present age some knowledge of the laws of nature is an essential part of the mental outfit which no cultivated man should lack. He need not know much, but he ought to know enough to learn more. To him the forces of nature ought not to be an occult mystery, but a chain of causes and effects with which, if not wholly familiar, he can at least claim acquaintance; and the same principle applies to every other leading branch of knowledge.

SOCIETIES AND ACADEMIES.

PARIS.

Academy of Sciences, October 26.—M. Bouchard in the chair.—E. L. **Bouvier**: The phenomena which characterise the change of nest in the ant *Messor barbarus*. A detailed account of the curious habits of these ants when exchanging nests.—M. **Gouy**: The constitution of the electric charge at the surface of an electrolyte.—Armand **Gautier**: Remarks on the second International Congress for the Repression of Fraud in Food and Drugs, held at Paris, October 18 to 23.—J. **Guillaume**: Observations of the sun made at the Observatory of Lyons during the second quarter of 1909. Observations were possible on sixty-three days, the results being summarised in three tables showing the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—Charles **Nordmann**: The temperature of β Perseus (Algol). Taking 6000° as the temperature of the sun, the application of Planck's law leads to 22,900° as the temperature of Algol. This is nearly identical with the temperature (23,800°) found previously by a totally independent method.—M. **Javelle**: Halley's comet. Observations of the comet made with the large equatorial at Nice. On October 12 it appeared as a small round nebulosity, $10''$ to $15''$ in diameter, with a central nucleus of the fourteenth to fifteenth magnitude.—R. **Jarry-Desloges**: Observations on the surface of the planet Mars. Two diagrams accompany this paper, showing the details perceived during July, August, and September, 1909.—G. **Athanasiadis**: The influence of temperature on the phenomena of polarisation in the electrolytic valve. The potential difference, producing a definite current in the electrolytic valve, diminishes as the temperature increases.—L. **Gay**: The vapour pressure of mixed liquids. A new demonstration and generalisation of the formula of Duhem-Margules.—G. **Belloc**: The emission of gases by heated metals. A definite volume of gas can be extracted by heating a metal such as steel to a definite temperature in a vacuum. If the metal is allowed to cool, the vacuum being maintained, a re-heating to the same temperature after an interval of some days gives rise to a fresh amount of gas, and this process can be continued; even after seven heatings small amounts of gas continue to be evolved.—Maurice **Coste**: The transformations of selenium. Exact measurements of the density of selenium submitted to various treatments have been made.—E. **Cornec**: Cryoscopic study of the neutralisation of some acids.—Maurice **Barrée**: The points of transformation of the copper-aluminium alloys as determined by a study of the variation of electrical resistance with temperature.—Georges **Darzens** and M. **Rost**: Hexahydrophenylacetylene and hexahydrophenylpropiolic acid. Starting this hexahydroacetophenone,

$C_6H_5.CO.CH_3$, this was converted into $C_6H_{11}.CCl:CH_2$ by the action of phosphorus pentachloride, and from this hexahydrophenylacetylene is obtained by the action of potash. The sodium derivative of this, with carbon dioxide, gave sodium hexahydrophenylpropiolate, some derivatives of which are described.—H. **Arsandaux**: Contribution to the study of the laterites.—Marin **Molliard**: Can the amines serve as food for the higher plants? Contrary to the results of Ville and of Lutz, the author's experiments lead to the conclusion that none of the amines can act as food substances for the higher plants.—I. **Borcea**: The origin of the heart, the vascular migratory cells, and the pigmentary cells in the Teleostea.—A. **Imbert**: The fatigue produced by rapid movements.—C. **Fleig**: The action of radio-active mineral waters and of artificial serums on the survival of organs or isolated cellular elements of the body.—Maurice **de Rothschild** and Henri **Neuville**: Remarks on the okapi.—A. **Monvoisin**: The acidity of the milk of tuberculous cows. The low acidity of tuberculous milks depends principally upon the diminution in the amount of casein present.—Alfred **Angot**: The earthquake of October 20–21, 1909. The seismograph records at the Parc Saint-Maur Observatory indicate that this earthquake, no mention of which occurs in the newspapers, must have been very violent. Its epicentre was probably in the Himalayas or neighbouring mountainous regions.—E. A. **Martel**: The subterranean river of Labouiche or La Grange (Ariège).—V. **Crémieu**: A new determination of the Newtonian constant. The torsion-balance method, described in a previous paper by the author, gives a value of $K = 6{\cdot}674 \times 10^{-8}$, the accuracy estimated being of the order of 1 in 10,000.—H. Hildebrand **Hildebrandsson**: Some remarks on the temperatures of summer in various parts of Europe.

CALCUTTA.

Asiatic Society of Bengal, October 6.—J. C. **Brown**: Stone implements from the Tongyueh district, Yünnan Province, western China (with a short account of the beliefs of the Yünnanese regarding these objects). A description of a representative series of twelve stone implements selected from numerous specimens recently examined in Tongyueh is given. Nine of these specimens are fashioned from varieties of jadeite, the other three being cut from red slate-like, white quartzite, and igneous rocks. The Yünnanese attribute a celestial origin to these stones, which they believe to possess occult medicinal properties and to be efficacious in the treatment of obdurate diseases in which the medical treatment has failed to produce any beneficial results. Descriptions of the specimens are subjoined.—H. E. **Stapleton**: (1) An alchemical compilation of the thirteenth century A.D.; (2) contributions to the history and ethnology of north-eastern India, i.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 4.

ROYAL SOCIETY, at 4.30.—(1) The Development of *Trypanosoma Gambiense* in *Glossina palpalis*; (2) A Note on the Occurrence of a Trypanosome in the African Elephant: Colonel Sir David Bruce, C.B., F.R.S., Captains A. E. Hamerton and H. R. Bateman, R.A.M.C., and Captain F. P. Mackie, I.M.S.—On the Perception of the Direction of Sound: The Lord Rayleigh, O.M., F.R.S.—The Diffraction of Electric Waves: Prof. H. M. Macdonald, F.R.S.—On the Mechanism of the Absorption Spectra of Solutions: Robert Houstoun.—(1) Note on the Spontaneous Luminosity of a Uranium Mineral; (2) The Accumulation of Helium in Geological Time, II: Hon. R. J. Strutt, F.R.S.—On the Physical Properties of Gold Leaf at High Temperatures: J. C. Chapman and H. L. Porter.—The Dimensions and Function of the Martian Canals: Dr. H. C. Pocklington, F.R.S.

LINNEAN SOCIETY, at 8.—Some Account of the Field-botany of Namaqualand, Damaraland, and South Angola: Prof. H. H. W. Pearson.

RÖNTGEN SOCIETY, at 8.15.—Presidential Address: C. E. S. Phillips.

FRIDAY, NOVEMBER 5.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.30.—Huxley Memorial Lecture. The North European Race: Prof. G. Retzius.

MONDAY, NOVEMBER 8.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Journeys in Bhutan: J. Claude White.

TUESDAY, NOVEMBER 9.

ZOOLOGICAL SOCIETY, at 8.30.—Some Living Shells, their Recent History, and the Light They Throw on the Latest Physical Changes in the Earth: Sir Henry H. Howorth, K.C.I.E., F.R.S.—The Asiatic Fishes of the Family Anabantidæ: C. Tate Regan.—On a Small Collection of Mammals from Egypt: J. Lewis Bonhote.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Single-phase Electrification of the Heysham, Morecambe and Lancaster Branch of the Midland Railway: J. Dalziel and J. Sayers.—The Equipment and Working-Results of the Mersey Railway under Steam and under Electric Traction: J. Shaw.—The Effect of Electrical Operation on the Permanent-Way Maintenance of Railways as Illustrated on the Tynemouth Branches of the North-Eastern Railway: Dr. C. A. Harrison.

THURSDAY, NOVEMBER 11.

ROYAL SOCIETY, at 4.30.—*Probable Papers:* The Vacuolation of the Blood-platelets—An Experimental Proof of their Cellular Nature: H. C. Ross.—Further Results of the Experimental Treatment of Trypanosomiasis—being a Progress Report to a Committee of the Royal Society: H. G. Plimmer and Captain W. B. Fry.—*Hillhousia mirabilis*, a Giant Sulphur Bacterium: G. S. West and B. M. Griffiths.—The Modes of Division of *Spirochaeta recurrentis* and *S. duttoni* as observed in the Living Organism: H. B. Fantham and Miss A. Porter.

MATHEMATICAL SOCIETY, at 5.30.—Annual General Meeting.—(1) The Ordinal Relations of the Terms of a Convergent Sequence; (2) The Application to Dirichlet's Series of Borel's Exponential Method of Summation; (3) Theorems relating to the Summability and Convergence of Slowly Oscillating Series: G. H. Hardy.—Notes on Synthetic Geometry: Prof. W. Esson.—Kummer's Quartic Surface as a Wave Surface: H. Bateman.—The Green's Function in a Wedge, and Other Problems in the Conduction of Heat: Prof. H. S. Carslaw.—The Envelope of a Line cut Harmonically by two Conics: J. L. S. Hatton.—On a Case of q-Hypergeometric Series: Rev. F. H. Jackson.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Presidential Address: Dr. Gisbert Kapp.

FRIDAY, NOVEMBER 12.

PHYSICAL SOCIETY, at 8.—On the Absorption Spectrum of Potassium Vapour: P. V. Bevan.—Some Further Notes on the Physiological Principles underlying the Flicker Photometer: J. S. Dow.—Exhibition of a Colour-perception Spectrometer: Dr. F. W. Edridge-Green.—Tables of Ber and Bei and Ker and Kei Functions, with Furthur Formulæ for their Computation: H. G. Savidge.

ROYAL ASTRONOMICAL SOCIETY, at 5.

THURSDAY, NOVEMBER 11, 1909.

THE INTERNAL COMBUSTION ENGINE.

The Gas, Petrol, and Oil Engine. By Dugald Clerk, F.R.S. Vol. i. New and revised edition. Pp. ix+380. (London: Longmans and Co., 1909.) Price 12*s.* 6*d.* net.

MR. DUGALD CLERK originally published this book under the title of "The Gas Engine" in 1886. Ten years later it reappeared in enlarged form as the "Gas and Oil Engine." It has now been found necessary, the author tells us, to re-write practically the whole of it, and in doing so the further change of dividing it into two volumes has been made. This is in itself evidence of the development of science and practice that has taken place during the last twenty-three years. The two new volumes are to be called "The Thermodynamics of the Gas, Petrol, and Oil Engine," and "The Gas, Petrol, and Oil Engine in Practice." It is the first of these volumes which is now issued. It is ostensibly a book on the thermodynamics of the gas engine, and it is as such, therefore, that it must be examined and discussed. We may say at once that it is quite unlike any other book on thermodynamics that we remember to have read. Its appeal must be to the comparatively small number of engineers and physicists who are familiar alike with modern practice in gas-engine work and with some of the most recent results in physics. To the experimenter in this important field of work, it will be invaluable as containing in compact form a record of the latest experiments as well as an occasional commentary upon them from the author's standpoint.

It interested us to compare the present volume with Mr. Dugald Clerk's book on the gas engine issued in 1896. We were the more interested in such a comparison because of the change that has come to the point of view of so many workers on account of later knowledge of the physical properties of the gases concerned in the gas-engine cycle. Mr. Clerk's point of view has also changed materially. The author remarks on p. 200:—

"Some things, however, have been definitely settled. Holborn and Austin's investigations have placed it beyond doubt that the specific heat of steam and carbonic acid increases considerably with increase of temperature, and that a small increase occurs with oxygen and nitrogen. Nernst's investigations have proved that the dissociation of steam and carbonic acid at about 2000° C. is unexpectedly small."

When the 1896 edition was published, and until a much later date, Mr. Dugald Clerk was disinclined to accept the contention of the French physicists that specific heat increased with temperature, and the thermodynamic part of that volume, which is, we notice, reproduced with but little change in the first 118 pages of the present one, was based on the constancy of specific heat. After reproducing this earlier work, Mr. Dugald Clerk now adds:—

"Throughout the present chapter the working fluid has been assumed to be dry air obeying perfectly the laws of Charles and Boyle; its specific heat has also been assumed to be constant throughout the temperature range. . . . It is now known that the specific heat of air is not quite constant between 0° and 1400° C. . . . The mean Kp between 100° C. and 1400° C. is about 8 per cent. higher than that between 100° and 200° C. . . . But it must be remembered that the efficiencies and mean pressures determined by these calculations for ideal air are not the efficiencies and mean pressures which would be proper to the actual working fluid. . . . Meantime, however, it may be taken that the reasoning and conclusions reached in this chapter are valuable when properly used."

From p. 119 onwards the author takes into account the variability of specific heat with temperature. Indeed, in virtue of its importance, the greater part of the book is devoted to the consideration of this matter and of the associated problems.

Practically all recent work is described at more or less length, and particular stress is laid on the important work carried out on gaseous explosions at the Royal College of Science, on the initiation of Prof. Perry. Mr. Dugald Clerk is able to reproduce a great deal of this experimental work which had not previously been published, and he analyses the results obtained with great skill and infinite patience. It seems a pity that the record of these experiments has not previously been published, and we can only surmise that their importance was not realised adequately, perhaps because the experimenters, Messrs. Bairstow and Alexander, did not bring out their points with the emphasis at Mr. Dugald Clerk's command. How far the accuracy of these experimenters will stand the test of time remains to be seen; the virtue that led Mr. Dugald Clerk to refer to them at such length is that they are the only experiments so far known from which can be obtained a series of cooling curves under various conditions of pressure and temperature. We anticipate that practical results of real use will be obtained from this work.

At the end of the volume the author reproduces the very valuable 1908 report of the Gaseous Explosions Committee of the British Association. It includes a description of Mr. Dugald Clerk's "zig-zag" experiments. It also criticises them, and gives reason for thinking that they may contain an error of as much as 10 per cent. The committee remarks, "If there be systematic error in Mr. Clerk's work it seems most likely that it lies in the estimate of heat loss," and proceeds to indicate a way in which this error can be corrected. It is very curious to read this report at the end of Mr. Dugald Clerk's book, when, on turning to his own account of these very experiments, he omits to discuss any correction of the kind. We think that it would have been better if some notice had been taken of the committee's remarks, although it may well be that to have done so would have led to such a mass of extra work that any author might shrink from it.

We are so grateful to Mr. Dugald Clerk for this interesting volume that we do not wish to press too hard the main criticism to which it is liable, viz. that it is insufficiently edited, that a tight enough grip is not held upon the subject, and that the style is not such as to make it easily readable.

THE DIAMONDS OF SOUTH AFRICA.

Die diamantführenden Gesteine Südafrikas, ihr Abbau und ihre Aufbereitung. By Dr. Ing. Percy A. Wagner. Pp. xviii+207. (Berlin: Gebrüder Borntraeger, 1909.) Price 7 marks.

AMONG the numerous works that have appeared on the subject of South African diamonds, the book before us is worthy of a very high place. The author has examined the diamond-bearing rocks and their relations during a visit to South Africa, and has studied the materials brought home in the laboratories of Prof. Rosenbusch in Heidelberg, and under Prof. R. Beck at Freiberg, to the latter of whom the work is dedicated.

The record of previous literature at the beginning is very full and complete, comprising the titles of 138 memoirs and books, besides general references to periodical publications. The distribution and character of the various "pipes" are clearly described, and the series of comparative ground-plans drawn to scale on p. 7 is very striking and instructive. The second division of the book contains an admirable account of the various minerals found in the pipes, of which minerals no fewer than about thirty species are described. In his chapter on the petrography of the country, the author adopts the views of Carvill Lewis and Bonney concerning the important part played by the rock to which the first-named author gave the name of "Kimberlite"; but besides the form of the rock first described from the Kimberley district, Dr. Wagner indicates the existence of a variety much richer in mica (biotite), which occurs in dykes in Orangia and northern Cape Colony. These rocks have been carefully studied by the author, who gives chemical analyses of them and the results of investigations under the microscope, illustrated by two plates containing photographs of rock-sections.

Since the discovery of diamonds enclosed in masses of eclogite (the "griquaite" of Beck) in the pipes of South Africa—a discovery announced in this country by Sir William Crookes and Prof. Bonney in 1907—special interest attaches to the various fragmentary rock-masses which occur so frequently in the "blue and yellow grounds" of the South African mines. The author devotes especial attention to the characters of this diamond-bearing eclogite, and cites the case of a similar rock having been found in the Bingera diamond field of New South Wales, as related by Mr. G. W. Card. It is interesting to notice that not only diamond but crystalline plates of graphite have been found by Harger and by Beck, enclosed in the eclogite masses. Various other rock fragments and mineral aggregates occurring with the eclogite masses are described in detail. The evidence of the existence of diamond enclosed in olivine, and of microscopic diamonds distributed through kimberlite, is also discussed, and the bearing of all these and other facts on the vexed question of the origin of the diamond is considered. The whole of the observations bearing on the subject appear to us to be stated very clearly and impartially.

We naturally look in this work for some account of the new diamond-fields of German South-west Africa, but at present the information upon the subject appears to be somewhat meagre. According to the only scientific account of the district which has as yet appeared, the diamonds occur in an undisturbed formation of Cretaceous Sandstone. This sandstone, according to Merensky, however, consists in great parts of grains of chalcedony and agate, derived from an amygdaloidal diabase, and it is this rock which is regarded by him as the original source of the diamonds. In 1908 this diamond-field had yielded a great number of small diamonds (usually four or five to the carat) of the aggregate weight of 39,762 carats and of a value of 550,000*l*.

The later chapters of the book deal with the methods of mining the "blue ground," and the different kinds of treatment to which it is subjected in order to extract the diamonds. A number of photographs of the various workings, and of the machinery employed, adds to the interest of these chapters, the information in which has been apparently obtained from trustworthy sources. The work closes with some interesting statistics showing the weight and value of diamonds yielded by each of the mining districts, and the average value per carat in each case. From 1898 to 1908 nearly thirty-one millions of carats were obtained in South Africa.

A LOST OPPORTUNITY.

The Stone Ages in North Britain and Ireland. By the Rev. Frederick Smith. With an introduction by Prof. Augustus H. Keane. Pp. xxiv+377; illustrated. (London: Blackie and Son, Ltd.) Price 6*s*. net.

THE problem of the Stone ages is one that is full of complications. The greater part of it yet remains unsolved, for the sum of our actual knowledge of the conditions of Palæolithic man is as nothing in comparison with our ignorance. By small degrees advances are made. It is found, for example, that in other continents the remains of analogous culture stages bear that striking resemblance to those of our own that is one of the most surprising features of the study of prehistoric man in all periods. But such additions to knowledge, interesting as they are, help but little to enable us to picture the lives of the men whom they concern. The advance must of necessity be slow, for it is given to few to be able to read in nature's writing the very incomplete record of early man. While empiricism may make a lucky shot now and then, it can be only to the trained and reflective searcher that we must look for any effectual progress. Of such trained and industrious men there is no lack, and their accumulated experience, sifted by a master, might even now be brought into line for the less instructed public. Meanwhile, we have enthusiasts, like the Rev. Frederick Smith, who spend years in gathering specimens and deducing theories from them, and present us with ample volumes, like the present one, well printed and fully illustrated, and with this for the moment we must be content.

Mr. Smith is an amateur in all senses of the word.

His love for every stone he has found appears throughout the whole book, and his grief at the loss of one specimen, of which he has only kept a drawing, is almost pathetic. That he is an amateur in the other sense is clearly shown by his method of presenting his case. A careful statement of the evidence which leads him to attribute this or that specimen to the Palæolithic or any age is hardly to be found, while his attitude is one of pure dogmatism with regard to the artificial character of the stones he is principally dealing with. It is manifestly unsafe to judge of such a point as the latter from a drawing alone, and that is all the reviewer has in the present case. But it is not unjust to assume that in Mr. Smith's own drawings of the stones he is dealing with, all the features that lead him to think them to be "artefacts" are shown at their best. Yet to the unprejudiced eye, familiar with man's handiwork in stone under primitive conditions, whether prehistoric or modern, there are very few in Mr. Smith's book that could safely be pronounced "artefacts."

This may appear to be a hard saying, and in a limited degree it is so, for, in default of some evidence, it is hard to think that the majority of the stones represented in Mr. Smith's figures show any signs of human handiwork. Nevertheless, it is quite conceivable that they may be the best that Scottish Palæolithic man could produce. But what is wanted is something approaching proof of human intention in the fashioning of them. Mr. Smith, in short, has mistaken a much-loved hypothesis for fact. As hypothesis, no one would have found fault with his volume. He has spent much time and many words, moreover, in demolishing phantoms; for instance, he is apologetic that his "implements" of basalt and similar rocks do not show the familiar "bulb of percussion," so common in flint tools, and yet he surely must know that the fracture of flint differs essentially from that of basalt or granite; he adduces (p. 14), as proof of the Palæolithic age of the stones, the fact that he never encountered a polished weapon, as if all tools or weapons of the later ages were polished; most assuredly the majority are chipped only. He refers to glacial striæ in support of the same contention, and for this we would commend to him the vast series of Neolithic scrapers with glacial markings that have been collected by Dr. Allen Sturge. Two pages of text and three figures are devoted to a single chipped flint, described (and doubtless rightly) as accidental by "a Cambridge expert." Here a claim is made that the facets of the surface are made to fit the ball of the thumb. As if the human hand had no power of adaptability! It is very likely that this and other flaked flints, whether the flaking be natural or artificial, will be found to fit the ball of the thumb, but the virtue lies in the thumb, not in the flint.

One other instance of Mr. Smith's arguments is worth quoting. He was distressed that the flaking on one of his flints had been set down as due to "thermal" causes. This criticism he meets by the statement that he had watched some of his flints pass through all the rigours of Scottish winters for no less a period than twenty long years, and that they showed no signs of thermal flaking at the end of it. Arguments of this kind can only convince the converted, and even the support of Prof. Keane, enthusiastic as he is, will hardly suffice to carry conviction to the unbiassed. The chapter on Ireland is of a piece with the rest. The author's naïve surprise at finding in Ireland precisely the same forms he had been finding in Scotland recalls to one's memory the letter from Egypt of the late Mr. Auberon Herbert, who found there the very same broken edges to flint flakes that he had seen in England, though it must be confessed that Mr. Smith does not go to quite the same lengths as Mr. Herbert.

A book of this kind makes one sad. Working on a stable foundation, Mr. Smith's pertinacity and enthusiasm might have enabled him to add his mite to the sum of our knowledge of early man. He has chosen, on the other hand, to follow a will o' the wisp.

CHEMICAL TECHNOLOGY.

(1) *L'Industria delle Materie Grasse.* Vol. i. I Grassi e le Cere. By Dr. S. Facchini. Pp. xxiii+651. (Milan: Ulrico Hoepli, 1909.) Price 6.50 lire.

(2) *Gomme, Resine, Gomme-resine e Balsami.* By Dr. Luigi Settimj. Pp. xvi+373. (Milan: Ulrico Hoepli, 1909.) Price 4.50 lire.

(3) *Analisi Chimiche per gli Ingegneri.* By Dr. Luigi Medri. Pp. xiv+313. (Milan: Ulrico Hoepli, 1909.) Price 3.50 lire.

(4) *Die Chemische Industrie.* By Gustav Müller unter mitwirkung von Dr. Fritz Bennigson. Pp. viii+488. (Leipzig: B. G. Teubner, 1909.) Price 11.20 marks.

(5) *Chemical Industry on the Continent: a Report to the Electors of the Gartside Scholarship.* By Harold Baron. Pp. xi+71. (Manchester: University Press, 1909.) Price 1s. net.

(6) *Laboratory Guide of Industrial Chemistry.* By Dr. Allen Rogers. Pp. ix+158. (London: Constable and Co., Ltd., 1908.) Price 6s. net.

(1, 2 and 3) THESE three volumes belong to the well-known and excellent "Manuali Hoepli." Dr. Facchini's treatise is the first volume of a series which, when completed, will cover the whole ground of the industry of fats, oils and soaps. It deals with the general chemistry of the fats and waxes, and the methods used in their analysis. It is a concise but fairly complete summary of the information included in the larger treatises on the subject, and should prove a useful book of reference in cases where the larger works are not available. The same remarks apply to the treatise on gums and resins by Dr. Settimj, which necessarily is in the main but a well-arranged and useful abstract of Tschirch's standard handbook.

Dr. Medri's little book on analysis is a compilation designed specially for the use of engineers rather than chemists. It summarises the methods of analysis of air, water, cement materials, combustibles—solid, liquid and gaseous—and of several of the principal metals and alloys in general use. There is also a short chapter on explosives.

(4) Councillor Gustav Müller's essay on chemical industry contains a wealth of information hitherto scattered in official publications and technical journals, and only to be gleaned with difficulty. There is little doubt that it will become an indispensable book of reference to the chemical merchant and manufacturer, as well as a guide to the works manager, on all economical and statistical questions concerning his industry. The early chapter on general economic development contains a brief history of the growth of chemical industry in different countries, with full statistics for all the different branches dealt with. Valuable information is collected with regard to patents and trade marks, and the existing "trusts" or "Kartels." A chapter covering eighty pages, on the legal control of the industry, includes a discussion of patent laws, factory acts, workmen's insurance and health regulations, and includes details of the tariff rates for Germany and of trading treaties with other countries. In the second part of the work, a chapter is devoted to each individual branch of chemical industry, and here complete statistics of imports and exports for several years past are collected for each substance considered. The whole work is excellently arranged, and cannot but prove of the very highest utility.

(5) Mr. Harold Baron's report is the outcome of a tour undertaken in 1905 as Gartside scholar in the University of Manchester. Under the tenure of these scholarships, each scholar has to select some industry or part of an industry for examination, and investigate this comparatively in the United Kingdom and abroad. The present report is an account of a visit to a large number of chemical and textile works in Belgium, northern France, and Germany, with comments on their character and organisation. The report makes interesting reading, and contains a good deal of information likely to prove instructive to those not well acquainted with Continental chemical works and their methods. The description given of the wonderful works of the Bayer Company at Elberfeld and Leverkusen deserves to be widely read. At Leverkusen the works are equipped with a water supply capable of producing thirteen and a quarter million gallons per day, the daily consumption of Cologne, a town with 400,000 inhabitants, being only thirteen million gallons daily. Some idea of the vastness of the colour works may be derived from the fact that the azo-colour department alone necessitates the use of 78,000 tons of ice per annum for cooling purposes. Mr. Baron's report is, on the whole, a just and accurate statement, but a few errors occur which need correction. For example, some of the statements with regard to the processes of manufacturing artificial silk need revision. Such errors were, perhaps, to be expected in a report prepared under the conditions of the present and dealing with a very wide field.

(6) Dr. Rogers's book and system we conceive to be based on entirely wrong principles. His scheme of training in industrial chemistry adopted at the Platt Institute, Brooklyn, consists in passing the students (the nature of whose chemical knowledge is rather uncertain) through a course of preparations and exercises under works-conditions in miniature. No attention is paid, apparently, to fundamental principles and process control. In less than 140 pages an enormous number of cookery-book recipes are given for the preparation of inorganic and organic compounds, pigments and lakes, driers, varnishes, paints and stains, soap and allied products, leather, wood pulp, and paper. The preparations are carried out with small works-plant, of which several illustrations are given in the book. We doubt the value of such a course in the education of a works-chemist, and consider that it would probably be to the detriment of the interests of his subsequent employers as tending to develop a blind and thoughtless empiricism. One of the most important factors in the success of a chemical works is a proper system of control, on scientific principles, of all stages of manufacture. We consider that it would be far better to work out a few—very few—manufacturing processes in detail, carefully studying by a proper system of tests the effects of varying the conditions, than to acquire a smattering of a large number of indiscriminately chosen works-operations. It is only by means of careful scientific control that chemical works in this country can hope to compete with foreign competition. To teach industrial chemistry as a series of cookery operations, involving the use of certain stock utensils, is likely to prove fatal in all cases, except in countries such as the United States, where high tariffs make economy of production a secondary consideration.

W. A. D.

HANDBOOKS ON ANIMAL STUDY.

(1) *Zoologia.* By Angel Gallardo. Pp. 474. (Buenos Aires: Angel Estrada Cia., 1909.) Price 6 dollars.

(2) *Einführung in die Biologie.* By Prof. Karl Kraepelin. Pp. viii+322. (Leipzig and Berlin: B. G. Teubner, 1909.) Price 4 marks.

(3) *The Freshwater Aquarium and its Inhabitants.* By Otto Eggeling and Frederick Ehrenberg. Pp. vii+352. (New York: Henry Holt and Co.; London: G. Bell and Sons.) Price 8s. net.

(4) *Bilder aus dem Ameisenleben.* By H. Viehmeyer. Pp. viii+159. (Leipzig: Quelle und Meyer, n.d.) Price 1.80 marks.

(5) *Die Schwarotzer der Menschen und Tiere.* By Dr. O. von Linstow. Pp. viii+144. (Leipzig: Quelle und Meyer, n.d.) Price 1.80 marks.

(1) IT seems almost axiomatic that if a text-book of zoology begins by dealing with the obscure details and overwhelming nomenclature of cytology, it is a bad book. Bad because organisms are not aggregates of cells, and because such a method is essentially an inverted one in relation to the grasp of the beginner. In this text-book, written for the School of Pharmacy at Buenos Aires, the inversion appears complete. The end of the book is an introduction showing how zoology has been pursued in the republic, whilst the beginning is occupied by Karyokinesis, modes of segmentation, and other difficult subjects. After general histology, we have evolution and transformation-theories treated in that diagrammatic and

dogmatic way that is so destructive of their interest and advancement. The classification of animals adopted, Unicellularia, Radiata, Bilateralia, is almost as antique as that of the animal and vegetative functions maintained in the earlier part of this book. The "worms" are reduced to a type characterised by a trochosphere-larva and nephridia, whilst, for the benefit of medical students, only parasitic forms are described. The book is, in fact, a compilation of the "cram" order, and is devoted mainly to the structure and life-history of parasites. In no single instance is the scale of a figure given.

(2) In spite of the very large output of books on biology, there is still no modern work in which the factors of the life of plants are correlated with those of animal life in a broad and intimate manner. This text-book is, perhaps, as near an approach to such a treatment as the limits of a cheap school-book allow, and in the second edition just issued the breadth of treatment has been increased. The contents are divided into three parts. First come the relations of organisms to environment; then follows an account of structure and functions; lastly, a brief chapter on psychology and anthropology. Between the last two parts is a short, clear account of evidence for the theory of descent. Of these three sections, the first is undoubtedly the most novel for a work of this kind. It is very doubtful whether the author has not attempted to compress far too much information into these pages, and certainly the attempt to teach the subject from such a book as this without simplifying its contents would be disastrous. The work itself appears to be a well-illustrated summary of facts, but is as hard to assimilate as a concentrated foodstuff. The teacher must supply the zymogen.

(3) In this American book the experience of the professional "aquarist" and importer has been combined with that of the practised amateur. The result is a volume full of interesting matter and of practical suggestion to naturalists and teachers. The introduction of many beautifully coloured fish from Texas, Florida, India, and other countries into the northern States enables a very great choice of interesting subjects to be drawn upon. The climbing perch, the "shooter" that brings its prey down by spitting, and the lovely Paradise fish Macropodes, the nests of which are readily constructed in captivity, are some of the more striking oriental fish introduced by one of the authors. The Reptilia and Amphibia are also fully considered, and the book concludes with most useful advice on the choice of natural and artificial foods. In these days of experimental stations and school laboratories, such a practical guide as this should be very welcome. The illustrations are excellent, and the only fault we have to find with the work is its weight, which not only splits the binding, but tires the hand.

(4) The value of this little book lies in the fact that its descriptions of the occurrence and habits of ants are largely written down from the author's observation. The sketches are thrown into a conversational form so as to appeal to children. The various beetles found in ants' nests are fully considered and figured, and the author is evidently acquainted with the literature of the subject. We can heartily recommend this little book as a record of long and patient observation, and as a very useful *résumé* of the most distinctive and interesting features in the life of these highly organised animals.

(5) Dr. von Linstow's popular account of human and animal parasites ends badly from the beginning. On the cover of the book there is a gruesome picture of infected pond-life, and a tragedy occurs on almost every page. The contents describe some appalling cases of the course of parasitical diseases, and whilst we fully acknowledge the abundant knowledge and clear exposition that has gone to its making, we can hardly believe that such a treatise is appropriate to a series suitable for children and people generally. Pan certainly has a terrifying aspect when seen thus, and it would have relieved the depression if the available prophylactic and remedial measures could, as far as possible, have been described.

ELEMENTARY PHYSICS.

(1) *An Introduction to Physical Science.* By Dr. F. H. Getman. Pp. ix+257. (New York: J. Wiley and Sons; London: Chapman and Hall, Ltd., 1909.) Price 6*s*. 6*d*. net.

(2) *An Elementary Course in Practical Science.* Part iii. By C. Foxcroft and S. J. Bunting. Pp. 64. (London: G. Philip and Son, Ltd., n.d.) Price 6*d*. net.

(1) THE book by Dr. Getman is intended for those students who, owing to little knowledge of physics, find it difficult to understand lectures on general chemistry. It deals in a brief manner with all the usual sections of physics, with the exception of sound. It is in many respects an admirable book. The chief laws and principles are in most cases very clearly expressed. As an example of this, attention may be directed to the concise and unambiguous treatment of the distinction between "mass" and "weight." The diagrams are good, and logical order is preserved. There is no doubt that a student thoroughly conversant with the contents would have little difficulty with his chemistry from a physical point of view. On the other hand, we think that for several reasons the book itself presents difficulties. The definitions, particularly in the first chapter or two, are sometimes rather loose. Matter is apologetically defined as "that which occupies space," a statement which is worthless. Surely a better provisional definition is "matter is that which has weight," and then the extension of "weight" to "gravitational attraction" could follow at a later stage. Again, a solid is defined as "a body which at ordinary temperatures does not change its shape under slight changes of pressure." This is untrue. There is no distinction, except in degree, between solids and fluids in this respect. The terms "stress" and "strain" are insufficiently defined, being merely given as alternatives for force and distortion respectively.

We feel, too, that the cutting out of detail, which the author admits in the preface, has been carried too far. The descriptions of experiments are thus in many cases vague, and in a few instances actually misleading. For example, in the determination of the latent heat of water, we are told that "a *weighed* quantity of dry ice is now added to the water." Such procedure would, needless to say, be fatal to the accuracy of the measurement. It may be mentioned also that in describing the measurement of an electric current with a tangent galvanometer, the author neither mentions the very necessary adjustment of the coils parallel to the magnetic meridian, nor does he show the bearing of the strength of the earth's field on the absolute value of the current. Altogether, from the point of view of practical physics the book leaves much to be desired. Indeed, the author goes so far as to suggest that the practical part may be entirely omitted.

A further point should be mentioned. Although there is an extensive set of very suitable numerical examples given, practically no specimen examples are solved. It is very doubtful whether an average student could, unaided, successfully attack them. When it is remembered that it is mainly by the frequent use of numerical and practical exercises that the principles of physics are most easily and thoroughly instilled into the mind, it will be recognised how serious are the above omissions.

(2) This book is the third of a series on simple physical measurements, &c., and is drawn up on the same general method as the previous ones, viz. to leave as much as possible to the student's initiative and common sense. The exercises, although still very simple, are of a somewhat higher standard, and include further measurements in the subjects previously dealt with, and a few experiments in elementary chemistry. This method of teaching is somewhat novel, and probably the correct one. Where time is a consideration, however, it may not be practicable.

OUR BOOK SHELF.

A Brief Course in the Calculus. By W. Cain. Pp. x+280. (London: Blackie and Son, Ltd., 1909.) Price 6*s.* net.

THIS is a new publication of an American book, and deals with both the differential and the integral calculus. Following the more recent English treatises on the same subject, the author begins with an introduction on graphs, in which he confines himself to the simplest cases of the usual functions. The value of such an introduction would, perhaps, be enhanced if the reader were shown how to draw quickly even rough graphs of such functions as x^2+x+1, $(x^2-1)/(x+2)$, &c., indeed, of *rational* functions. The point of view of the author may be obtained from his own words (p. 27):—"The above examples represent loci whose asymptotes are easily determined by inspection. For other cases, particularly where the asymptotes are inclined to the axes, advanced treatises on the Calculus must be consulted."

Derivatives are introduced through the notion of a limit. After the derivative of x^n has been established (without using the binomial theorem), discussion of the slope of a curve and of rates follows. If the graphical part had been developed more fully, the latter notions might have taken precedence of and led up to derivatives. Such a mode of treatment would perhaps have given a greater air of reality to the derivative in the case of readers who have time for only a short course in the calculus, and whose power of mathematical perception has not been highly trained. The author, however, has good authority for the order he adopts, and he keeps well in view the needs of those who want a careful study of the subject as well as those who are likely to apply their knowledge to geometry, mechanics, and physics. He has dealt fully and carefully with the outstanding parts of the subject, and works out many examples; it is doubtless in consistency with his whole aim that he does not give a very large number of examples to be worked out by the reader, in this respect differing from most authors of mathematical books. To teachers and students who prefer a smaller number of examples, and need a work in which the method and province of the calculus are presented by a careful writer, the book can be recommended as likely to be a useful introduction to the subject. P. P.

The Life of a Fossil Hunter. By Charles H. Sternberg. Pp. xiv+286; with 46 plate illustrations. (New York: Henry Holt and Co.; London: George Bell and Sons, 1909.)

THIS is a simple and readable story of the experiences of a fossil hunter in the wild west of North America. As Prof. Osborn remarks in his brief introduction, "the revivification of the past" by the discovery of fossils "is attended with as great fascination as the quest of live game." No one has met with greater success in such pursuits than Mr. Charles Sternberg, the well-known collector of extinct vertebrates, who now recounts some of his experiences during the past forty years; and he has produced a small book which will be read with pleasure by all who are acquainted with the fine specimens which he has obtained for several of the great museums. The well-printed text is illustrated by a large number of inset plates representing scenery, fossils discovered by the author, portraits, and several excellent restorations of extinct reptiles from the American Museum of Natural History, New York.

In the early days of his explorations, Mr. Sternberg was exposed to danger from the Indians whose country he invaded, and there are several interesting stories of his adventures both with them and the settlers. In later years, and even under the most improved conditions, the hardships have still remained considerable, for the most fruitful regions for fossils are always those most destitute of vegetation, where the whole face of the rock is exposed and can be closely scanned. The suffocating nature of the dust and the alkaline or saline condition of most of the available water supply always prove troublesome, and the laborious excavation of fossils in such circumstances, beneath a burning sun, involves real enthusiasm for the work. Mr. Sternberg, after long experience, has brought his methods to perfection, and he gives interesting illustrations of the manner in which the most fragile skeletons can be disinterred from the rock without injury. He began by collecting fossil leaves from the Dakota Cretaceous sandstone. Afterwards, with the encouragement of the late Prof. E. D. Cope, he obtained mosasaurs and fishes from the chalk of Kansas. Then he made several successful trips to the Permian of Texas, in which he discovered numerous new reptiles and labyrinthodonts. Finally, he has worked the Laramie Cretaceous formations of Wyoming, and the Loup Fork Tertiary formation of Kansas. Besides enriching the museums of America, Mr. Sternberg has contributed many important specimens to those of Europe, especially to the Palæontological Museum of Munich and the British Museum. The latter is indebted to him for a skull of Triceratops, a skull and a skeleton of Pteranodon, several Mosasaurians, some fine chalk fishes, and a mandible of a primitive Mastodont (*Tetrabelodon dinotherioides*). He is still in the field, now accompanied by his sons, whom he has trained to follow him.

A. S. W.

The Book of Nature-Study. Edited by Prof. J. B. Farmer, F.R.S. Vol. IV. Pp. viii+210. (London: The Caxton Publishing Company, n.d.) Price 7*s.* 6*d.* net.

The fourth volume of this attractive publication is devoted entirely to botany. The descriptions by Dr. W. H. Lang of some common plants flowering in the spring and summer appeared in the previous volume; the continuation refers to plants that flower later in the year and others of special morphological interest, such as the honeysuckle, dodder, sundew, and types of trees. The Scots pine serves as a representative gymnosperm, while a brief account of pollination and seed dispersal closes Dr. Lang's contributions. His precise and orderly descriptions provide excellent models for a student to emulate.

To Dr. W. Cavers has been entrusted the somewhat difficult task of preparing an interesting account of the cryptogams, and in this he is very successful. He adopts a less formal method of description than Dr. Lang, and by confining himself merely to the more important characters, he is enabled to direct attention to a large number of species. Most of the indigenous ferns and fern allies are noted, and the more striking mosses and liverworts. Lichens form the subject of a separate chapter, but algæ are omitted, and only outlines of the fungal groups are indicated. This section and the former one are confined to morphology as distinct from ecology, which provides the bulk of the third section contributed by Miss C. L. Laurie, although the heading, "Woodland Vegetation," appears in the contents. The ecological section suffers from a want of definition of the main objective. The descriptions of the moors, commons, and heaths are quite definite, perhaps somewhat brief, but the interpolation of parasites and saprophytes in the middle of plant associations presents an unnecessary confusion of ideas. The chapter on woodland vegetation is very instructive, albeit the paragraphs are somewhat disjointed, and no definite tree formations are fully described as such.

The illustrations are numerous and excellent; the coloured plates of single plants, notably of the honeysuckle, are admirable specimens of reproduction, and the plain photographs are practically as effective for their purpose. Two photographs of lichens, the woodland photographs by Miss Tidman, and the illustrations of the mistletoe and goat-willow are perhaps the choicest: but it is somewhat invidious to draw distinctions, as the contributors include Dr. O. V. Darbishire, Mr. H. Irving, and Mr. Chalkley Gould.

Éléments de la Théorie des Probabilités. By Émile Borel. Pp. viii+190. (Paris: A. Hermann et Fils, 1909.) Price 6 francs.

Like all Prof. Borel's works, this is a very pleasant book to read. It is in three parts, dealing respectively with discontinuous problems, continuous problems, and those in which *a priori* probabilities are involved. The second part contains, among other things, a useful sketch of Gauss's theory of errors; and the third gives some applications to statistics and biology. Some of the problems are quite amusing; for instance, "Pierre plays écarté with a stranger, who turns up a king the first time he deals. What is the probability of his being a professional cardsharper?"

Magnetic Storms.

The last English mail which arrived in India brought the newspapers containing the account of the magnetic storm of September 25, and in the *Times* Sir Oliver Lodge's opinion on the cause of such storms is given. It appears, however, that three of the statements contained in that account are not entirely supported by experimental and observational evidence, and would not be subscribed to by those who have recently been working at the problems of atmospheric electricity.

(1) Sir Oliver Lodge remarks:—"Some of them" (electrons from the sun), "especially at the times of the equinox, may come down near the equator. Those which journey to the Poles are accompanied by an opposite current in the crust of the earth from the equator to the Poles, and this it is which disturbs the telegraphs, being picked up or tapped by them *en route.*" Now if a large quantity of negative electricity were suddenly added to the upper atmosphere, and this induced a corresponding charge of positive electricity on the earth's surface, it would of necessity disturb the existing potential gradient in the atmosphere.

The extent of the disturbance can be roughly calculated by treating the earth's surface as an infinite plane. Suppose that the electrons moving in the upper atmosphere and adjacent space are uniformly distributed; their electrostatic and horizontal magnetic effect at the earth's surface will then be the same as if they were confined to a plane parallel to the surface of the earth. Let the surface density on the plane be σ and the velocity of the ions in the plane v; H will then be changed by $2\pi\sigma v$. Now Dr. Chree states (Nature, September 30) that during the magnetic storm H varied by more than 740 γ; for convenience let us take the change in H to be only 700 γ, *i.e.* 0·007 electromagnetic unit. Hence $2\pi\sigma v=0{\cdot}007$, or $\sigma=0{\cdot}007/2\pi v$. If σ is measured in electrostatic units this becomes $0{\cdot}007\mathrm{V}/2\pi v$, where V is the velocity of light. The electrostatic field between the charged plane and the earth would be $4\pi\sigma$, *i.e.* $4\pi\times 0{\cdot}007\mathrm{V}/2\pi v$ or $0{\cdot}014\mathrm{V}/v$. Expressing this field in volts per metre, we have $0{\cdot}014\times 300\times 100\mathrm{V}/v$, *i.e.* $420\mathrm{V}/v$. Now v cannot be greater than V, hence the smallest value of the field would be 420 volts per metre. This value is more than four times greater than the normal value of the potential gradient in the atmosphere, and it is of the opposite sign. This calculation is not supposed to be quantitatively accurate, but it gives in a simple way the order of magnitude of the effect. Hence it is seen that the large electrical charges which would be required to produce the magnetic effects observed, even if they moved with the velocity of light, would be easily recognised by their effect on the potential gradient. For many years instruments have been in use in different parts of the earth giving continuous records of the potential gradient in the atmosphere, but, so far as I am aware, no effect of a magnetic storm has ever been reported. Such an instrument is in use in Simla. On the day of the storm the weather here was perfect, so that if any effect of the kind had taken place it would have been clearly seen; but, as a matter of fact, there is absolutely nothing on the record to distinguish the period of the magnetic storm from the periods on either side of it: the potential gradient was entirely normal throughout September 25 and 26. It would therefore appear that the great earth currents associated with magnetic storms are not, as Sir Oliver Lodge suggests, due to induced charges.

(2) Sir Oliver Lodge further says, regarding the electrons:—"Those which enter the atmosphere elsewhere act as nuclei for condensation of moisture, and by screening the sun's rays are probably responsible for some of the dull and overcast weather." This statement is apparently based on a misconception of Mr. C. T. R. Wilson's experiments on the condensation of water vapour on ions, for these experiments do not afford any real support to

such an idea. Mr. Wilson's results showed that ions may become the nuclei for condensation, but only when the air is both dust-free and supersaturated four-fold. An infinity of ions in dusty air, or in air supersaturated three-fold, would not cause clouds, and as neither dust-free nor supersaturated air have ever yet been met with in the atmosphere, it is difficult to see how electrons from the sun could produce cloudy weather.

(3) These considerations apply, but with still greater force, to Sir Oliver Lodge's next sentence:—"Local thunderstorms are also a not unlikely result." This is not the place to go into the controversy over the Wilson-Gerdien theory of thunderstorms, but it ought to be pointed out that very strong reasons have been put forward for doubting that the condensation of water on ions plays any part in thunderstorms. GEORGE C. SIMPSON.

Meteorological Office, Simla, October 21.

The Identity of Certain Large Birds on Egyptian Vases.

IN looking to-day for an archæological reference in my friend M. Jean Capart's valuable volume on "Primitive Art in Egypt" (English edition), I noted that he has determined certain birds, delineated on a series of decorated vases, as ostriches. The vases I refer to are to be found on p. 116, Fig. 88; p. 118, Fig. 91; p. 119, Fig. 92; p. 120, Fig. 93; p. 121, Fig. 94; and p. 123, Fig. 96. I venture to suggest that the birds intended to be represented are not ostriches, but flamingos. The inbent beak, the dorsal body-contour, the horizontal ventral region, and the long, lanky legs, uncovered by feathers in the tibial region as in ostriches, all so characteristic of the flamingo, are delineated with great truthfulness on a large scale on the vase illustrated on p. 123, Fig. 96. The crosier-staff-like head is common to all the drawings I have indicated. Although the representation of the bird on p. 120, Fig. 93, is rather too small and ill-defined to base much upon, the curvature of the neck is yet more that of a ciconiiform than of a struthious bird. Indeed, on p. 119, Fig. 92, the group of birds at the right-hand corner of the vase is actually in proximity to water, which would hardly be the case if the artist intended it for one of ostriches; while on the vase illustrated on p. 121, Fig. 94, the four birds delineated have very characteristic horizontal flamingo tails, especially the individual on the extreme left of the row, in which it is spread. These attitudes are in striking contrast with those of certain other large birds included in the zoological group on the rocks of Upper Egypt, reproduced on p. 204, which must be admitted to represent ostriches, at the first glance, from the attitude of their legs in walking, their plumage contour, and their straight beaks.

The above suggestion I have made during the past two or three years to several Egyptologists, who have recognised its valency; but as I have seen nowhere this emendation, which I believe it to be, recorded, I think it may be of interest to give it publicity, inasmuch as the ethnographical deductions to be drawn from these rude pictures can be correct only if the artist's intention has been accurately interpreted. HENRY O. FORBES.

The Museums, Liverpool, October 31.

November Meteors.

THE absence of moonlight during the Leonid epoch of the present year will be favourable for observations of this historic shower. For determining on which of the three dates of November 14, 15, and 16 it may occur, calculations made by the writer point to the night of November 16 as that of the maximum, when, as was the case on the corresponding night of last year, the number of meteors radiating from the Sickle may be found by observers to be considerable. The following are details as to this and also other showers that become due during the remainder of the month of November:—

Leonid epoch, November 16, 8h. G.M.T. This shower is of the sixteenth order of magnitude, having its principal maximum on November 16, 15h.; other maxima take place on November 16, 10h. and 18h., and November 17, 21h.

Epoch November 21, 9h. 30m., shower of fourth order of magnitude. The principal maxima occur on November 19, 21h. 15m., and November 20, 18h. 30m. Two other maxima occur on November 20, 2h. 30m. and 5h. 30m.

Epoch November 21, 17h. This shower, which is of the fifteenth order of magnitude and immediately follows the former, has its maxima on November 21, 21h., and November 22, 11h. 30m.

Epoch November 26, 1h. 30m. This shower, of third order of magnitude, has two principal maxima, on November 26, 15h., and November 27, 2h. There is another maximum on November 27, 5h.

Epoch November 29, 20h. 30m., of third order of magnitude; has its principal maximum on November 29, 17h., with an earlier maximum on November 29, 3h. 30m.

Dublin, November 8. JOHN R. HENRY.

The Absence of a Lunar Atmosphere.

WITH reference to Mr. Alexander Johnson's letter on this interesting subject, I should like to point out that the theory of radiation pressure is not applicable to gases. Beyond a certain range of minuteness, the effect of radiation pressure on particles diminishes, and the size of a particle on which the repulsive force of light is at a maximum is vastly greater than molecular magnitudes. As this is very important, I quote certain numerical determinations given by Prof. Arrhenius ("Worlds in the Making," pp. 97, 98):—

(1) Diameter of a totally reflecting sphere which would be in equilibrium near the sun under the opposing forces of gravitation and radiation pressure = 0·0015 mm., the specific gravity of the sphere being the same as water.

(2) For radiation pressure to be effective, the diameter of the particle must exceed 0·3 of the wave-length of the incident radiation. If smaller than this, gravitation predominates.

(3) Radiation pressure is at a maximum when the diameter of the particle equals the wave-length of the incident light (*e.g.* 0·5 μ for the blue-green region about λ 5000 A.U.).

(4) In the case of sunlight, which is not homogeneous, Prof. Arrhenius gives 0·00016 mm. as the diameter of particles on which the effect is greatest.

As regards the absence of a lunar atmosphere, it seems that we must fall back on the kinetic theory of gases and attribute it to the gradual escape of the more swiftly moving molecules into the surrounding space.

CHARLES W. RAFFETY.

Wynnstay, Woodcote Valley Road, Purley, Surrey,
November 1.

Pitchblende as a Remedy.

As there is now no longer the least doubt as to important cures being effected by means of radium, the question arises whether crude pitchblende would not also have beneficial effect if applied in the case of minor chronic ailments. Perhaps one of the readers of NATURE will be able kindly to give some information on this subject. The very minute proportion of radium in pitchblende need be no real objection. If we substitute, in the case of pitchblende, grams for milligrams and days of application for so many minutes, a disparity of one million is soon made up, and there may be some action, although perhaps different from that of a pure radium salt. Moreover, we must expect a beneficial influence from minute quantities of radio-active substance if the assumption is to be finally proved that certain thermal waters owe much of their virtue to such traces. In addition to raw pitchblende, a possible utility of pure (yellow) uranium oxide might also be considered. H. WARTH.

SOUTH AFRICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE seventh annual meeting of the South African Association for the Advancement of Science opened at Bloemfontein on Monday, September 27, under the presidency of the Governor, Sir Hamilton Goold-Adams. The advantage of Bloemfontein for such a conference, in that it is in the centre of South Africa, was observable in the number of busy men who were able to run down from Johannesburg, Pretoria, and Kimberley for the occasion, to whom the usual two days and two nights' journey in the train necessary to travel from one centre to another would have been prohibitive. The meeting was the most successful so far held, from the fact that the Governor, the municipality, the Press, and the citizens generally, united in welcoming the delegates from the various centres, and in showing appreciation for the objects of the association.

In the opening address the president struck the dominant note of the meeting, namely, that science is not of purely academic interest, but that the results won by scientific men could be understood by the unlearned if they tried, and that the results could be applied to everyday life with material benefit. The text of the address was the "Application of Chemistry in Agriculture." The mining industry has a very important bearing on the prosperity of the country, "yet agriculture must be considered as the main and permanent foundation upon which the future progress of the nation must rest."

The acting mayor, Mr. A. E. Parfitt, in welcoming the delegates, said, "I daresay that from a sanitary point of view this town excels all others in South Africa," a wonderful statement in view of what the town was like only a few years ago. This fact was more fully brought out by Dr. Tomory, medical officer of health for the town, later on in his paper on "Recent Methods of Water Purification," in which he dealt with the merits of slow sand filtration and the American methods of rapid chemical treatment; the Bloemfontein system is a compromise between the two.

Prof. W. A. D. Rudge, of Grey College, Bloemfontein, president of the section of astronomy and mathematics, opened the sectional meetings at the Normal College buildings on September 28 with an address on the "Genesis of Matter." Mr. Hugh Gunn, Director of Education in the Orange Free State, president of the education section, took for the subject of his opening address "The Problem of Rural Education." He considered this to be the most exigent question of the moment. Farmers had done their best, but the badly provided farm schools, staffed with one teacher, whose emoluments were poor, and whose qualifications corresponded, were inadequate. Rural schools were regarded as being on the lowest rung of the educational ladder. He calculated that barely one-quarter of the area of South Africa was provided with school facilities, and that 80,000 children of school age were not attending school. Of this number he thought two-thirds lived in the rural districts. He wished to abolish single-teacher schools, and to replace them with three-teacher schools. This could be done by providing transport facilities. A beginning had been made in the Orange Free State with satisfactory results, and he hoped to see the system extended.

Dr. C. F. Juritz, of Cape Town, opened the section devoted to chemistry and geology with an address on "Agricultural Chemistry." The following are the more important papers read in the various sections. Unfortunately, the sections were reduced to three, and had subsequently to be divided to enable all the papers to be read, hence some confusion ensued in regard to placing the papers in their proper section.

Water vapour on Mars, J. de Fenton; notes on the geology of Natal, J. A. H. Armstrong; revised list of the mammals of South Africa, E. C. Chubb; puberty rites of the Basuto, and prehistoric African fauna and flora as evidenced by African philology, Rev. Father Norton; maize breeding, R. W. Thornton; cultivation of maize, J. Burtt-Davy; solar radiation, H. E. Wood; the great snowstorm of August, 1909, H. E. Wood; the Breede River irrigation works, T. E. Scaife; notes on the recent magnetic storm, G. W. Hopkinson; the flora of Portuguese East Africa, T. R. Sim; the vegetation of the southern Namib, Dr. R. Marloth; lime and milk, R. Pape; the composition of milk in Cape Colony, St. C. O. Sinclair; notes on the fauna and flora of Sarawak, J. Hewitt; mental healing, Right Rev. Bishop Chandler; the value of the practice and teaching of hygiene in schools, Dr. Targett-Adams; the salt pan of Haagenstad, G. W. Cook; the bearing of recent theories on the nature of the earth's interior on the question of deep mining, Prof. E. H. L. Schwarz; itacolumite from Swaziland, Prof. G. H. Stanley; observations on the vascular system of *Hemitelia Capensis*, H. G. Morris; notes on the anatomy of Widdringtonia and Callitris, W. T. Saxton; the principles of the naturalisation of forestry, C. Robertson; architecture, H. Baker; the relative growth of our white and black population, J. M. P. Muirhead; classics in our secondary schools, Dr. J. Brill; biography of Mohlomi, traveller, witch-doctor and chief, A. C. McGregor; the tercentenary of the telescope, H. B. Austin; the English language and literature in South Africa, Prof. Stanley Kidd; education in a Swiss canton, A. M. Robb; practical education, T. Lowden; agricultural training of natives, Hobart Houghton; weights and measures for South Africa, R. T. A. Innes.

Members of the association were taken round the new buildings of the Grey University College and the Grey School. The admirable building stone from the Bloemfontein commonage and the northern Free State allows the local architects to build elegant buildings; but this may become somewhat of a disadvantage, and leads often to cases where the effect of a window from the outside is considered more than its usefulness in the inside. A second excursion was to the military cantonments at Tempe, but the most instructive outing was to the dry farm at Groot Vlei, where lucerne, fescue, burnet, sainfoin, and other fodder plants, besides cereals, are grown without irrigation. A large area of the farm is planted with the Australian salt bush, which thrives admirably; the soil does not appear to be brak here, but, rather, is unproductive on account of its being clogged with fine silt.

Two popular lectures were given in the Town Hall, one on "Celestial Chemistry," by Dr. C. F. Juritz, and one on "Explosives," by Mr. W. Cullen, of the Modderfontein dynamite factory. At the close of the latter the British Association medal and cheque of 40*l*. were presented to Dr. Harry Bolus, the botanist.

At the annual general meeting the report of the council was presented, which showed a large decrease of membership owing to the prolonged depression in South Africa. To meet the decrease in income it was proposed to abolish one of the permanent offices, either the Johannesburg or the Cape Town one; it was also proposed to issue the Transactions in monthly parts. In view of the opening of the Union Parliament in Cape Town next year by His Royal Highness the Prince of Wales, it was proposed to hold the 1910 meeting in Cape Town at about the same date. His Excellency Sir Hamilton Goold-Adams was asked to offer the presidency of the association to His Royal Highness.

Mr. Lowden brought forward the subject of a prize scheme, which was discussed at some length both at Cape Town and at Johannesburg, and urged that something should be done to induce young students to take up science subjects. He suggested that if nothing else could be done, the association should offer at least a medal for the first two students matriculating in each science subject, and that if the funds of the association were not available, a subscription should be raised for the purpose. After some discussion the president stated that he would like to mark in some way his appreciation of the work of the association and the honour done him in electing him the president for the year, and he thought he could do this by offering to defray the cost of the die of a suitable medal for the purpose suggested by Mr. Lowden. On the proposal of Mr. Innes, seconded by Dr. Juritz, it was resolved to accept this offer with many thanks, and to name the awards the "Goold-Adams" medals.

The Bloemfontein Museum deserves an article to itself; the members of the association were shown over the collections, and from cupboard and cranny objects of the utmost value were unearthed, including meteorites, stone and iron ones, Karroo fossils, early printed books, engravings, manuscripts, Bushmen implements, and a complete quagga skin. The collections urgently need proper accommodation, and it is hoped that the visit of the association brought home to the authorities some realisation of what a valuable asset for the town they had in their museum.

Dr. R. T. A. Innes was elected honorary secretary for the Transvaal and Free State, and Dr. C. F. Juritz for Cape Colony and Rhodesia, Dr. R. T. Lehfeldt honorary treasurer.

At the close of the meeting forty-five members left for a train and wagon trip to Basutoland, the railway authorities having placed a special train at the disposal of the association.

AMERICAN CAVE VERTEBRATES.[1]

PROF. EIGENMANN has brought together in an attractive and copiously illustrated quarto volume the results of his investigations on the cave fauna of America, upon which he has been engaged for many years. He points out that each cave is a separate environmental unit requiring special consideration, but all share to a greater or less extent certain common features, viz. the reduction or total absence of light and the relative constancy of other physical conditions, such as temperature.

The blind cave vertebrates form a very mixed faunistic group, derived from a variety of epigean ancestors. It appears, however, that "a certain predisposition in habit and structure must be present to enable a species to dispense with light and to live in caves." No mammals appear to have become especially adapted for permanent cave life, though, of course, many spend a large part of their lives in such situations. They may be "twilight animals," but they still have normal eyes. The same is the case with birds, and there are also no cave reptiles, which is remarkable when we consider that many snakes and lizards are blind, and burrow underground.

It is amongst the amphibia and fishes that true cave vertebrates are to be found. Two of the North American salamanders, of the genus Spelerpes, which habitually live in caves, still possess what appear to be normal eyes, while two others, of the genera Typhlotriton and Typhlomolge, have their eyes quite degenerate, resembling in this respect the European Proteus. The Amblyopsidæ are the typical North American cave fishes. "All the members of this family, eight in number, have degenerate eyes; five have mere vestiges; six permanently live in caves; one is known only from a spring, and another from open streams." More remarkable is the fact that in Cuba two sightless fishes, Stygicola and Lucifuga, belonging to a marine family many of which are blind, have become adapted to the fresh waters of caves.

Space forbids us to follow the author in his detailed and interesting discussion of the origin of the cave fauna. We may note, however, that he seems inclined to regard blindness as an antecedent rather than as a consequence of cave life, for it is only animals which are already accustomed to find their food by the sense of touch or smell which could ever establish themselves in complete darkness. In Amblyopsis, and other blind fishes, great numbers of special tactile organs are developed, especially about the head, and these serve for ascertaining, by disturbances in the water, the whereabouts of prey.

In the case of the loss of colour, however, which is such a general character of animals living in perpetual darkness, it is different, and Prof. Eigenmann regards this character as due in the first place to the direct influence of the environment upon the individual. To quote his own words, "The bleached condition of animals living in the dark, an individual environmental adaptation, is transmissible, and finally becomes hereditarily fixed." This conclusion is based upon the fact that in Amblyopsis the bleaching takes place even when the young are reared in the light. "Natural selection cannot have affected the coloration of the cave forms, for it can be of no consequence whether a cave species is white or black. It could only affect the coloration indirectly in one of two ways: first, as a matter of economy, but since the *individual* is in part bleached by the direct effect of the darkness, there is no reason why natural selection should come into play at all in reducing the pigment as a matter of economy; second, Romanes has supposed that the colour disappeared through the selection of correlated structures, a supposition he found scarcely conceivable when the variety of animals showing the bleached condition was considered." It appears to us that these conclusions are of great interest and importance, and that Prof. Eigenmann has made out a strong case for the inheritance of acquired characters in this instance. In the case of Proteus it appears that the bleached condition has not yet become hereditarily established, for this animal becomes darker when exposed to the light. Possibly, after all, the inheritance or non-inheritance of acquired characters is largely a question of time, or, perhaps better, of the number of successive generations which have responded ontogenetically to the particular stimulus which evokes the character in question.

A great part of the volume is devoted to the consideration of the structural changes which accompany the degeneration of the eyes, and the author has given us a large amount of very valuable information on this difficult subject, including a detailed account of the development of the eye of Amblyopsis. From many points of view this interesting work will well repay a careful perusal.

ARTHUR DENDY.

THE PRESERVATION OF NATURAL MONUMENTS IN GERMANY.[1]

THE German Government has been, for the last two years, organising a national system for the preservation of the natural monuments of the country. During the last year the scheme has developed in comprehensiveness, and has produced gratifying results. There are now forty local committees, and at the end of last year the first Congress for *Naturdenkmalpflege* in Prussia was held at Berlin. A considerable number of valuable reports has been issued; the present volume, edited by the energetic Government Commissioner for the Care of Natural Monuments, Prof. Conwentz, contains a report of the congress, and a general report on the work of the past year up to March 31.

---

[1] "Cave Vertebrates of America. A Study in Degenerative Evolution." By Prof. Carl H. Eigenmann. Pp. ix+241. (Washington: Carnegie Institution, 1909.)

[1] "Beiträge zur Naturdenkmalpflege." By Prof. H. Conwentz. Heft 3. Pp. 157–296. (Berlin: Gebrüder Borntraeger, 1909.) Price 2 marks.

The whole matter is another triumph of German organisation. Throughout the committees, which are interacting, are zoologists, ornithologists, botanists, geologists, and archæologists. The useful term "natural monument"—Alexander von Humboldt seems first to have employed it—includes practically everything indigenous which possesses scientific interest. In this report, for instance, which is well illustrated, there are accounts, not only of the *Porta Westfalica*, a human monument, but of interesting trees, "erratic" blocks of stone, moraines, diluvial sandstone formations, many characteristic specimens of the flora and fauna of the country, including various subdivisions, such as lichens and Lepidoptera. The term and the whole conception of the scheme are absolutely comprehensive. Many charts have already been prepared showing the local distribution of the "monuments"; such publications are of the highest scientific interest, especially when their subjects may still be counted on by the observer as existing in actuality.

It is to be hoped that this report may find its way to the hands of some English statesman. It gives an object-lesson of what can be done, and of how it may be done, to preserve the natural character of a country. In England the enclosure of sites and preservation of scenery too often result in the destruction of both fauna and flora. Where are the denizens, vegetable and animal, of White's Selborne? The present writer for many years had the privilege of research in a certain wild corner of Wensleydale which was as rich in rare plants and birds as any district in Great Britain. The ownership changed hands, and the whole of the wild life of the place was destroyed, first, by drainage for the purpose of making a coursing-ground, and later by operations connected with the water-supply of a great manufacturing town. This was vandalism no less brutal than the destruction of an exquisite statue.

It would be a profound satisfaction to lovers of nature if our country could be preserved in an efficient and comprehensive way. It is a work that could well be initiated by the Board of Agriculture. Dr. Conwentz, by the publication last year in English of his book "The Care of Natural Monuments, with Special Reference to Great Britain and Germany," has already given us a guide to both principle and execution. The present report—which can be read at one sitting—justifies his guidance.

A. E. Crawley.

THE MIGRATIONS OF PLAICE.[1]

The marking of plaice was commenced on the east coast of Ireland in August, 1905, and in a recent report Mr. G. P. Farran deals with such recaptures as have been made up to the end of 1907.

The principal plaice grounds on the coast of Ireland considered are within the areas prohibited to steam trawling, and the recaptures have been chiefly made by the local sailing trawlers and by line fishermen. In these circumstances it seems possible that here, as in other "prohibited" areas, some cases of recapture by steam trawlers may, for obvious reasons, be suppressed by the fishermen concerned.

Omitting certain fish liberated under unfavourable conditions, the total proportion of recaptured marked plaice stands at 46 per cent., from which Mr. Farran concludes that the local fishermen remove no inconsiderable portion of the stock of plaice on their fishing grounds. As an instance of how heavily a small area can be fished may be noted an experiment made in Skerries Bay. One hundred and eighty plaice were marked in April, 1906, out of which number no fewer than one hundred and nineteen, or 66 per cent., had been reported before the end of 1907.

In contrast to the long migrations which have been observed in the North Sea and at Iceland, very little tendency to extensive wanderings is shown by the plaice in these experiments. The majority were retaken within ten miles of the position of liberation. It is interesting to note that an inshore movement in the Dublin Bay area was evident in the autumn. A similar tendency has been noticed at this time of the year in some other parts of the British Isles, and is a well-known feature of the small plaice grounds off the Danish coast.

The choice of a suitable label for these experiments seems to have presented some difficulty. The German pattern of Dr. Heincke was found satisfactory for the size of fish most frequently met with, but unsatisfactory experiments were made with one or two other kinds. It seems curious that no attempt was made with the Petersen form of label, which has been successfully employed in the Danish, English, and other investigations, and, in Dr. Schmidt's classic experiments at Iceland, continued to be returned with the fish more than three years after their liberation.

Mr. Farran's mode of tabulating his data has certain disadvantages. The usual method adopted in recording recaptures is to take them in chronological order. Had this plan been followed instead of taking the consecutive numbers of the labels (an arrangement which seems to have little to recommend it), reference and comparison with the experiments of other investigators would have been facilitated.

NOTES.

Political, municipal, industrial, and philanthropic activities are liberally represented in the list of Birthday Honours published on Tuesday, but science and other intellectual interests receive scant recognition. There are six new privy councillors, six new baronets, and thirty-two new knights in the list. Among the privy councillors is Sir Henry Roscoe, F.R.S., and among those who have received the honour of knighthood are Prof. W. A. Tilden, F.R.S., and Mr. E. H. Shackleton, the leader of the recent Antarctic expedition. Prof. A. H. Church, F.R.S., has been appointed a Knight Commander of the Royal Victorian Order (K.C.V.O.). Mr. T. L. Heath has been promoted to be Knight Commander of the Bath (K.C.B.), and Dr. Sven Hedin has been appointed an honorary Knight Commander of the Indian Empire (K.C.I.E.).

The following is a list of fellows who have been recommended by the president and council of the Royal Society for election into the council for the ensuing year:—*President*, Sir Archibald Geikie, K.C.B.; *treasurer*, Mr. Alfred Bray Kempe; *secretaries*, Sir Joseph Larmor, Prof. J. R. Bradford; *foreign secretary*, Sir William Crookes; *other members of the council*, Dr. H. B. Baker, Dr. W. H. Gaskell, Prof. E. H. Griffiths, Prof. Horace Lamb, Prof. H. M. Macdonald, Major P. A. MacMahon, Dr. C. J. Martin, Sir Andrew Noble, Bart., K.C.B., Prof. W. H. Perkin, Prof. E. B. Poulton, Prof. J. H. Poynting, Lieut.-Colonel David Prain, C.I.E., Prof. R. A. Sampson, Dr. A. E. Shipley, the Right Hon. Sir James Stirling, Dr. A. Strahan.

We regret to see the announcement of the death of Dr. W. H. Dallinger, F.R.S., on Sunday, November 7, at sixty-seven years of age.

SIR GEORGE DARWIN, K.C.B., F.R.S., has been elected an honorary member of the Calcutta Mathematical Society.

DR. J. J. DOBBIE, F.R.S., director of the Royal Scottish Museum, Edinburgh, has been appointed principal chemist of the Government laboratories in succession to Sir T. E. Thorpe, C.B., F.R.S., who has retired.

THE date of the annual exhibition held by the Physical Society of London, which was fixed some time ago for December 10, has been altered to Tuesday, December 14, so that the exhibition may be open in the afternoon as well as in the evening.

A REUTER message from Berlin states that in the course of excavations conducted by the Museum of Silesian Antiquities at Ottitz, near Ratibor, a clay figure representing a nude female divinity was unearthed in a Stone-age dwelling. The figure is said to be the most ancient model of the human form in existence.

AT the meeting of the Junior Institution of Engineers on Tuesday, November 16, the presidential address, on "The Propelling Machinery of Warships," will be delivered by Vice-Admiral Henry J. Oram, C.B., Engineer-in-Chief of the Fleet.

THE opening meeting of the Illuminating Engineering Society will be held on Thursday, November 18, at the premises of the Royal Society of Arts, when the inaugural address will be delivered by Prof. Silvanus P. Thompson, F.R.S., the first president of the society.

SIR ARTHUR RÜCKER, F.R.S., and Prof. Arthur Schuster, F.R.S., both members of the board of advisers of the Department of Terrestrial Magnetism, Carnegie Institution of Washington, made official visits to the magnetic survey yacht *Carnegie* while at Falmouth, inspecting the instruments and methods of work.

A REUTER message from Washington states that the National Geographic Society has awarded its gold medal to Commander Peary. The subcommittee appointed to examine the explorer's records and proofs reported that they afford conclusive substantiation of his claim to have reached the North Pole, and this report was unanimously accepted by the board of managers. The society has passed a resolution referring to a subcommittee of experts the question whether any explorer reached the North Pole before 1909.

SIR WILLIAM WHITE, K.C.B., F.R.S., chairman of the council of the Royal Society of Arts, will open the new session of the society on November 17 with an address, the subject of which will be "An Imperial Navy." Before Christmas there will be four ordinary meetings of the society, at which papers will be read by Mr. T. Thorne-Baker, on "Phototelegraphy"; the Hon. R. C. Parsons, on "Resilient Wheels for Vehicles"; Mr. J. Buckland, on "The Destruction of Plumage Birds"; and Mr. H. Pearson, on "The Diamond Fields of Brazil." One meeting of the Indian section will be held, at which Sir James Wilson will read a paper on "The Punjab," and Mr. Samuel Simpson will treat "Agricultural Development in Nyasaland" at a meeting of the Colonial section. There will be one course of Cantor lectures; in them Mr. C. C. Turner will give a popular account of the progress which has been made in aëronautics.

THE Hampstead Scientific Society inaugurated a new astronomical observatory and meteorological station on the southern margin of Hampstead Heath on Saturday. Mr. P. E. Vizard presided over a large meeting of the society in Heath Mount School, and short addresses were given on the value of the astronomical work which could be done by Dr. F. Womack, and on the meteorological work by Dr. H. R. Mill. Sir Samuel Wilks, F.R.S., referred to the efforts the society had made to secure this observatory, which has cost about 250*l.* The party then visited the observatory, which, by the kind permission of the Metropolitan Water Board, is placed on the top of the covered reservoir on the highest point of Hampstead, 450 feet above sea-level. The small astronomical observatory has a revolving dome, and contains an 8½-inch equatorial reflector by Grubb, presented to the Society by Dr. Womack. A sidereal clock has been presented by Mr. E. Duveen, and it is hoped that a driving clock will be added later. The meteorological equipment consists of a barometer in the observatory, a Stevenson screen with the usual thermometers, a rain-gauge and a sunshine recorder, all of them exposed in an unexceptionable manner, so that the observations cannot fail to be of much value for climatological purposes. Interesting comparisons may be looked for between the Hampstead records and those taken only a few feet above sea-level in St. James's Park. In a district so subject as London is to partial visitations of fog and thunderstorms, the multiplication of trustworthy meteorological stations in representative positions is much to be desired.

ARRANGEMENTS have been made for an International Congress of Radiology and Electricity at Brussels on September 6, 7, and 8, 1910, in connection with the exhibition to be held there. The congress will be held in three sections, and the subjects to be dealt with will include the following. In the first section, general questions of terminology and methods of measurement in radioactivity, and subjects connected with ions, electrons, and corpuscles will be dealt with. The second section will be divided into various subsections, dealing respectively with fundamental theories of electricity, study of radiations (including spectroscopy, chemical effects of radiations, and other allied questions), radio-activity, atomic theory, cosmical phenomena (including atmospheric electricity and atmospheric radio-activity). The third section will be biological, and will be devoted to consideration of the effects of radiations on living organisms. The sections will deal with purely biological questions as well as with the use of various radiations for medical purposes, both for diagnosis and therapeutics. In order to ensure the success of the congress, committees have been formed in the various countries which will take part in the congress, and the following men of science have already consented to act as presidents of the committee in each country:—Prof. Lenard (Germany), Prof. Exner (Austria), Prof. Oötvös (Hungary), Prof. Castillo (Spain), Prof. Barus (United States), Prof. Langevin (France), Prof. Rutherford (Great Britain), Prof. Blaserna (Italy), Prof. Birkeland (Norway), Prof. Lorentz (Holland), Prof. Ferreira da Silva (Portugal), Prof. Hurmuzescu (Roumania), Prof. Lebedew (Russia), Prof. Arrhenius (Sweden), and Prof. Guye (Switzerland). Communications regarding the congress should be addressed to Prof. Rutherford or Dr. W. Makower at the University of Manchester; or to Dr. W. Deane Butcher, Holyrood, Ealing, London, W., for matters connected with the biological and medical section. Intending members should communicate directly with the general secretary, Dr. J. Daniel, 1 rue de la Prévôté, Brussels.

SOME of the friends and former pupils of the late Prof. Arthur Gamgee have thought that they could best mark their high appreciation of his great scientific attainments and single-hearted devotion to the prosecution of knowledge by forming a fund which should be of material benefit to his family—a widow and two daughters. Prof. Gamgee was widely known both in this country and abroad—he had, indeed, a European reputation—and it has seemed to those who have given their support to this fund, which was initiated some months ago, that it might be possible to augment still further the capital sum which it is desired should be raised if a knowledge of the objects of the fund was more widely spread, so that those who may wish to help should be invited to subscribe. It is not intended that any list of subscribers should be published. Towards the end of this month there will be a meeting of those who are in sympathy with the view that the raising of such a fund for his family would be the best and wisest appreciation of Prof. Gamgee's life-long devotion to science. The date and place of this meeting will be duly announced. Subscriptions may be sent to Prof. Arthur Schuster, Victoria Park, Manchester; Dr. A. D. Waller, Physiological Laboratory, University of London, S.W.; or Dr. G. A. Buckmaster, University College, London, W.C.

To the second half of the "Bergens Museum Aarbog" for 1909 Mr. Haakon Schetelig contributes an article on Norwegian antiquities received by the museum in 1908. The specimens include a roughly chipped stone implement from Vespestad; a bench of pine-wood from Hammer Church, Nordhordland; a portion of an iron sword, with silver mountings on the scabbard, from Sondhordland; a stone axe from Sogn; a flint javelin-head from Hardanger; and a bronze brooch from Lofoten.

In a paper published in vol. xxii., part i., of the Proceedings of the Royal Society of Victoria, Miss Morris and Miss Raff direct attention to certain features in the structure of the Australian lancelet, *Assymetron bassanum*, which have either escaped previous notice or have been inadequately described. The species in question occurs locally in depths up to 20 fathoms along the coasts of Victoria, and is commonly used in the laboratories of the colony in place of the typical Amphioxus. In another paper in the same issue Miss Buchanan commences a detailed account of the anatomy of Australian earthworms, dealing in this instance with the blood-vascular system, which is illustrated in the different species by diagrams.

In vol. xvii., No. 6, of the Proceedings of the Royal Physical Society of Edinburgh, Dr. Campbell Geddes directs attention to the extraordinary individual variation to be met with in the degree of development of the muscular impressions, crests, or tubercles of the appendicular skeleton of the human subject, and the inferences to be drawn therefrom. In the author's opinion such surface-details of the bones of the skeleton are only indirectly dependent on age, sex, and muscular activity, and are not, as Topinard believed, an index of the absolute muscularity of the individual. On the contrary, they depend directly upon, and therefore serve as an index to, the type of nutrition which the somatic cells of the individual enjoyed during life.

The origin and flora of the salt-marshes, salt-ponds, and fresh-water lakes of the northern coast of New Jersey have been studied by Mr. J. W. Harshberger, who gives the results of his investigations in the August issue of the Proceedings of the Academy of Sciences of Philadelphia. Such lakes and ponds are due to the advance of sand-dunes across the outlets of streams arising some distance inland. Most of the larger streams that have kept their outlets open are bordered for some distance from the sea with a characteristic salt-marsh vegetation. As the bars encroached on the outlets of the streams the water became brackish, and the salt-marsh plants gradually disappeared with the decrease of saltness. Finally, near the heads of several of the bays, as well as in some of the smaller ponds, the water becomes more and more fresh, and the salt-marsh plants are replaced by those accustomed to grow in or near fresh-water streams. Similarly, salt-ponds have become slowly changed into fresh-water lakes, with a corresponding alteration of the vegetation.

We have received the report on the progress and condition of the U.S. National Museum for the year ending June 30, 1908, in which detailed information is given as to the work accomplished on the new building up to that date, with illustrations of the complete structure. The progress of the work was considerably delayed owing to the failure of contractors to deliver the full complement of granite within a specified period. During the year under review the ethnological section of the museum was very largely augmented by collections illustrative of the natives of Borneo and the Philippines, the cliff-dwellers of Arizona, the Zuni Indians of New Mexico, and the Tahltau Indians of British Columbia. Mammals and birds from Malaya, the Philippines, and Costa Rica bulk largely among the additions to the zoological section, and the collections of fishes and invertebrates were largely augmented by the final distribution of the specimens obtained during the exploring cruise of the *Albatross* in the Pacific.

The nematodes come in for a large share of attention in the latest number of the *Zeitschrift für wissenschaftliche Zoologie* (Bd. 93, Heft iv.), in which Mr. E. Martini continues his studies on the subcuticula and lateral areas, and Dr. Fr. Bílek deals with the fibrillar structures in the muscle and intestinal cells of ascarids. Dr. Bílek's memoir, with its beautiful illustrations, constitutes a noteworthy addition to our knowledge of invertebrate cytology.

Messrs. Sanders and Co., Shaftesbury Avenue, have issued a very complete series of lantern-slides, 270 in all, illustrating spiders and their habits, a number of which we have had the opportunity of inspecting. The photographs were taken from nature by Mr. Richard Hancock, and show great manipulative and artistic skill. The series, of which a complete catalogue is also published, should be of great use to popular lecturers.

The *Journal of Morphology* for October (vol. xx., No. 3) contains two important cytological papers. In his "Observations on the Oökinesis in *Cerebratulus lacteus*," Naohide Yatsu describes the phenomena of maturation and fertilisation of the egg and its early cleavage stages. He deals especially with the behaviour of the "centriole," or, as English cytologists generally term it, the "centrosome," the latter term being used by the present author to designate the "centroplasm" which surrounds the "centriole," in other words, what is often termed in this country the "centrosphere." It is evident that the terminology of cytologists is in a somewhat confused state. Yatsu maintains the view that the middle piece of the spermatozoon carries a centriole into the egg at fertilisation, and that this gives rise by division to the cleavage centrioles.

Another paper in the *Journal of Morphology*—"Comparative Studies in Crustacean Spermatogenesis"—by M. Louise Nichols, besides the author's own observations, contains a useful *résumé* of the work of previous writers on the morphology of the crustacean spermatozoon. It seems that, according to Koltzoff, the curious immobile spermatozoon of the higher Crustacea is constructed very much on the principle of a cartridge. After the spermatozoon has become attached to the egg by means of its processes, the "capsule" explodes and drives the nucleus and centrosome into the egg. The same journal also includes an interesting account of the life-history and habits of *Chaetopterus variopedatus* by Mr. H. E. Enders, and a very full account of the development of the procephalic lobes of *Epeira cinerea* by Mr. A. E. Lambert, while Mr. Walter Meek contributes a description of the structure of the heart muscle of Limulus.

A PRELIMINARY revision of Philippine Myrtaceæ, by Dr. C. B. Robinson, published in the *Philippine Journal of Science* (Botany, vol. iv., part iii.), is primarily noteworthy for the number of species, just short of a hundred, described under the genus Eugenia. This is largely due to the incorporation under Eugenia of the segregates Jambosa and Syzygium, to which the greater number of species belong. Fully half the species are new types, and a considerable proportion of the remainder are endemic. Most of the Eugenias are trees yielding timber of value, although none supplies timber so commercially important as the myrtaceous tree *Xanthostemon verdugonianus*. Outside the genus Eugenia the family is poorly represented by a dozen species distributed over nine genera.

A NOTE on *Fomes lucidus*, one of the Polyporaceæ, contributed by Dr. E. J. Butler to the *Indian Forester* (September), deals with the probable parasitism of this fungus, as previously suggested by Dr. Raciborski. The author mentions a number of cases of fungal diseases, reported from different parts of India, on such different trees as Casuarinas, betel-palm, *Dalbergia Sissoo*, in which the source could not be definitely traced, but in all of which *Fomes lucidus* was found to be present; inoculation experiments are required to decide the question. In the same issue there are good illustrations of hills in the north Arcot division, Madras, showing the absence of tree growth in unprotected and protected but grazed areas as compared with the growth on a fully protected and partially planted area. For reproduction *Pterocarpus santalinus*, Red Sanders, proved to be better than *Terminalia tomentosa*, teak, or other species that were tried.

A FINE catalogue of plants, bulbs, and seeds has been issued by Messrs. Kelway and Son, of Langport, Somerset. The firm makes a special feature of hardy perennial plants, and their list of species in this section may be regarded as complete, but the catalogue is even more noteworthy in the selection of varieties offered under those plants that have been special objects of cultivation. The records of the Royal Horticultural and Royal Botanic Societies bear testimony to the splendid varieties of delphiniums, gaillardias, pyrethrums, and gladioli raised by Messrs. Kelway, and, above all, of pæonies, herbaceous, "imperial," and tree; the firm also raise their own forms of other favourites, such as zonal pelargoniums, hollyhocks, and phloxes. The catalogue cannot fail to arouse the enthusiasm of all garden-lovers; it is eminently practical in arrangement, description, and directions, is illustrated with choice photographic reproductions, and contains a few coloured plates taken in colour direct from the object.

AN account of the Peruvian National School of Agriculture is given in a new monthly publication entitled *Peru To-day*. The country possesses a rich soil and a climate enabling tropical products to be grown as well as those of the temperate zones. The coast is said to be well adapted to cotton raising; sugar and rice are also grown besides the ordinary cereal and other crops. A model vineyard has been started, and also an experimental sugar-cane station.

WE have received from Messrs. Pearl and Surface a paper on selection index numbers and their use in breeding, in which the authors discuss the case, commonly arising in practice, where it is desired to improve two or more features at the same time. Each of the several characters shown by the plant or animal receives a certain value, positive or negative. The sum of these values for each individual constitutes its index number. Those individuals with highest index numbers are then selected and used for breeding.

IN a recent number of the *Journal of Economic Biology* Mr. Southern describes a new species of Rhabditis, *R. brassicae*, discovered in a turnip in an advanced state of decomposition. The nematode worms commonly known as "eel worms" are found in water, soil, and decaying organic matter, and are responsible for a certain amount of damage to plants. Some genera, such as Tylenchus, are provided with a spine, by means of which the epidermis of the plant can be pierced and its juices sucked. In Rhabditis, however, this piercing apparatus is absent, and the author kept large numbers of the worms on the surface of a turnip for a month without the epidermis being affected; but once a way in was found, the worms were enabled to feed on the juices by means of their powerful sucking pharynx.

CONSIDERABLE attention is devoted to the culture of maize by the Transvaal Agricultural Department, and an account of the varieties most suitable is given by Mr. Burtt-Davy in the *Transvaal Agriculture Journal*. Dent maize is best for the main crops, as it usually gives the best yields and is in greatest demand; flint maize, on the other hand, is more suitable for districts where the rainfall is limited. Of the different varieties of dent maize Hickory King is most promising for the export trade, as it is purchased by corn-flour manufacturers, distillers, and brewers; by producing a choice grade of this variety still more profitable results may be obtained. Yellow varieties are grown for stock-feeding purposes.

THE quarterly issue of the *Eugenics Review* for October maintains the standard of former parts. In addition to the usual editorial notes and reviews, there is a short contribution by the honorary president, Sir Francis Galton, on the effects of small and persistent influences in moulding public opinion, and special articles on various aspects of eugenics. The note by Dr. Havelock Ellis directing attention to the sterilisation, on social grounds, of four mentally defective persons in Switzerland, and the Rev. J. H. F. Peile's discussion of the relation of the Church to the eugenic movement—a pressing and difficult problem—are, perhaps, of most general interest. It is to be regretted that the article by Dr. Slaughter, on selection in marriage, should be open to the criticism of Mr. Peile that much of the literature of eugenics is unconciliatory and dogmatic in tone. The adoption of a polemical style is inappropriate in a scientific contribution to the discussion of the subject, and defeats its own end in an article written for propagandist purposes.

THE *Century Magazine* for November contains a popular article, by Prof. Metchnikoff, on the utility of lactic microbes in the diet, their mode of action, and an explanation of the author's views on longevity.

THE winter session of the London School of Tropical Medicine was opened on October 26 by Mr. Whitelaw

Reid, the American Ambassador, when Prof. Osler delivered a masterly address on the progress of tropical medicine and the benefits resulting therefrom. Prof. Osler urged the great need there is for further extension in research on diseases of the tropics.

Considerable activity is being manifested in the attempt to cope with the plague of sleeping sickness in Africa. The Sleeping Sickness Bureau, under the direction of Dr. Bagshawe, has issued its tenth Bulletin, containing a summary of researches on trypanosome diseases, their pathology and treatment; also a progress report on the Uganda sleeping sickness camps from December, 1906, to November, 1908, compiled by Dr. Hodges, the principal medical officer, Uganda. The welcome statements are made that sleeping sickness is greatly on the decrease in Buganda kingdom, and that the drug atoxyl at least prolongs life, and in exceptional cases is curative. A bibliography of trypanosomiasis and tsetse-flies, embracing papers published prior to April, 1909, and compiled by Major C. A. Thimm, of the Sleeping Sickness Bureau, is in the press.

In *Symons's Meteorological Magazine* for October, Mr. C. Harding gives an interesting note, with diagram, of the summer weather (April–September) experienced in London and the suburbs during the last fifty years, prepared from the records of the Greenwich Observatory. The average number of warm days, on which a temperature of 70° and above was reached, was seventy-four; the greatest number of warm days was 127, in 1865. The last ten years, with the exception of 1906, have been cool. The average rainfall for the summer season is 12·29 inches —an amount which was exceeded this year by 1·80 inches.

A new barograph for recording minute and rapid oscillations of atmospheric pressure, invented by Mr. T. Shida, is described in the Proceedings of the Tokio Physical Society for April last. By a simple plan an aneroid barometer is made to record photographically; for the purpose of magnification, Kelvin's bifilar method is applied directly to a Bourdon tube, as used by Darwin and others. To protect the instrument, the whole system is enclosed in an air-tight case, with the exception of a small window provided with a lens for photographic registration. The case and tube have each a short piece of metal tube with stop-cocks communicating with the atmosphere. Specimens of the records are appended to the paper; the period of oscillation at Tokio was generally about six seconds, vibrations with the period of twelve seconds being most conspicuous. The author thinks that such observations may eventually explain the true cause of the pulsation of the ground.

A copy of "Studies in Practical Topography," by Mr. H. T. Crook, published by the Manchester Tactical Society, has reached us. Mr. Crook vigorously criticises the prepared sheets issued for some recent military examinations in a chapter entitled "The Land of (*d*)1," and gives three interesting topographical studies on Ruthin and the Clwydian range, Ilkley Skipton and the Pennines, and the Ribble Valley.

An excellent example of detailed geographical study of a small area appears in a paper, published in the *Mitteilungen* of the Vienna Geographical Society (vol. lii., No. 9), on the town of Graz. The author, Dr. G. A. Lukas, discusses the position, soil, water supply, climate, flora and fauna, and population of Graz and its neighbourhood with much detail, and the paper is accompanied by a geological map by Dr. Franz Heritsch. Specially interesting is the examination of the relation of local and outside conditions, and of the historical events which finally gave Graz the predominance over the equally well-situated Wildon.

A new series of calculating tables, by Dr. J. Peters, is announced (Berlin: Georg Reimer). The tables are to contain the products of all numbers of four figures by the numbers 1 to 100, so to multiply together two numbers of four figures it is only necessary to take two partial products from the tables and add them together, *i.e.* the multiplication is performed in two lines, which are written down from the tables.

A project for the formation of a museum of aërial navigation has been started under the auspices of the authorities of the Frankfurt Exhibition, the Frankfurt Aëronautical Society, the Physical Society, and other bodies in Frankfurt. It is pointed out that aërial navigation has a small past and a great future, and that the recent exhibition affords an excellent nucleus for a collection which can never be complete unless it is founded in the early days of the subject.

In view of the exaggerated importance attached to aëroplane record-breaking feats by the unscientific public, it is somewhat of a relief to turn to Mr. Gerald Biss's criticisms in the *Standard* of October 26. Great stress is laid on the power of individuality as a factor in present-day flights, it being pointed out that it was Mr. Latham's individuality which made his wonderful flight of the previous Friday possible. In a paragraph headed "When Aviation is Farcical," Mr. Biss says:—"The truth of the matter is, in a nutshell, that the progress of aviation has been greatly overwritten by ignorant enthusiasts and is still in the days of its earliest infancy. After the present boom, which will, I am sure, be far more short-lived than either the cycle or the motor boom, it will behove designers to sit down and work out the questions of automatic stability, vertical rising, compactness to the point of the practical, security against sudden dropping, and so on. . . ."

The view generally held that in the liquefaction of gases in the Linde or Hampson apparatus the cooling is due to the Joule-Kelvin effect has been attacked by Pictet in a series of articles which have appeared in the technical Press during the last half-dozen years. He has put forward an expression for the cooling which makes it depend on the work the gas does in overcoming the pressure in front of the expansion valve, and implies that it increases with increase of initial temperature and is almost independent of the fall of pressure. Messrs. W. P. Bradley and C. F. Hale, of the Wesleyan University of Connecticut, have made an extensive series of experiments on the cooling of the air in a liquefying apparatus in widely differing circumstances of pressure and temperature, and have found that the facts are qualitatively in agreement with the original theory, although there are quantitative differences to be explained, while they are diametrically opposed to the Pictet theory. The memoir is contained in the September number of the *Physical Review*.

In a paper entitled "The Elastic Breakdown of Non-ferrous Metals," read at the recent Manchester meeting of the Institute of Metals, Prof. C. A. Smith, of the East London College, describes the special strain-measuring appliance called the sphingometer, devised and used by him for the tension, compression, and torsion strips. There were five conditions which the instrument was required to fulfil, namely, (1) to determine the maximum, as well as the mean stress, on the material tested; (2) to be easily adapted to specimens of varying diameters; (3) to be easily adapted to specimens of varying length; (4) to measure accurately strains of at least one hundred-thousandth part of an inch; (5) to be of reasonable expense. The results of a large number of tests made with the instrument are given. These tend to prove that copper, aluminium, and other non-ferrous metals have very varying elastic properties, and it is consequently impossible to establish any definite law for elastic failure. It appears, however, that elastic failure always does take place according to a law which approximates closely to the maximum shear-stress theory.

IN an article on the development of modern road surfaces in the Journal of the Franklin Institute for October, Mr. W. H. Fulweiler divides the methods of applying tar into three general heads:—(*a*) Brushing with a hot coating of coal-tar and dusting it lightly with sand; in general use in France. (*b*) Painting the surface by machine and dusting with sand; in general use in England. (*c*) Coating the surface with a fairly heavy coating of hot tar or tar compounds, and then covering with a light coat of screening, the surface being finally rolled. The latter is the general system adopted in America, and seems to be better adapted to the rougher surface of American roads. A refined grade of tar, considerably heavier than that used in France or England, is used, having more body and greater binding properties, and the coating applied is about twice as heavy. A light coating of clean gravel or fine stone chips is then put on instead of sand and rolled, thus renewing the wearing surface and filling the voids better than can be done by the use of sand. The treatment produces deeper penetration and more lasting effect, and succeeds best on macadam roads. It is practically mud-proof, absolutely free from road dust, apparently proof against very heavy motor traffic, and is the most satisfactory for American conditions. The cost is higher than that of the French and English methods.

AN interesting pamphlet dealing with water-hammer in steam pipes has been issued by Mr. C. E. Stromeyer, chief engineer of the Manchester Steam Users' Association. According to the Board of Trade reports, water-hammer has been the cause of about 120 steam-pipe explosions. Mr. Stromeyer finds that nearly one-half of these have been due to the absence of drain-cocks on steam pipes, or to their injudicious use. A large number, chiefly on steamers, have been produced by admitting steam into pipes containing water. Others have occurred when water was admitted into steam pipes, or when steam condensed in them. Steam being admitted through valves on which water was resting, injudicious opening of valves having steam and water on both sides, and injudicious manipulations of steam valves, whereby plugs of water have been set in motion, have all contributed to swell the total of explosions. Mr. Stromeyer considers it inadvisable to lay down at present definite rules for the design of pipe arrangements in general, having been led to this conclusion by the fact that draining arrangements, designed to obviate explosions, have caused the majority of accidents, and also because in many cases of complicated pipe arrangements the water-hammer may often be attributed to any of the above-mentioned causes. Mr. Stromeyer complains of the insufficiency of the official reports of explosions having given him much difficulty in arriving at definite conclusions.

MR. W. B. CLIVE, of the University Tutorial Press, Ltd., has published a second edition of "First Stage Sound, Light and Heat." The book has been revised and re-written by Dr. R. W. Stewart, who has introduced a course of experimental work. The price of the book is 2*s.*

IN connection with the Winnipeg meeting of the British Association last August, the *Manitoba Free Press* published a series of illustrated biographical sketches of the president, Sir Joseph Thomson, F.R.S., the presidents of the sections, the evening lecturers, and the general officers of the association. These biographies have now been re-issued in pamphlet form at the price of 50 cents. Copies of the booklet can be obtained from Mr. A. V. Thomas, c/o *Manitoba Free Press*, Winnipeg, at 7½*d.* each.

WE have received a copy of the second part of vol. xiii. of the Transactions of the Leicester Literary and Philosophical Society. The booklet contains abstracts of lectures delivered before the society, the report of the council, and the annual reports of the sections of the society presented at the annual general meeting in May. The report states that the balance of the fund raised in connection with the visit to Leicester, in 1907, of the British Association has been voted to the council of the society for investment as the nucleus of a fund, the interest accruing from which is to be devoted in a manner to be decided by the council, annually, or at such times as the council may determine, to the development of local scientific knowledge, including that bearing upon the industries of the town. A cheque for 80*l.* has been received, and the council has appointed a special committee to consider and report as to the best means of applying the money in furtherance of the object intended.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN NOVEMBER:—

Nov. 11.	10h. 27m.	Mercury in conjunction with the Moon. (Mercury 1° 21′ S.).
16.	16h. 27m.	Venus in conjunction with the Moon. (Venus 0° 6′ S.).
,,	19h. 0m.	Vesta in conjunction with the Moon. (Vesta 1° 15′ N.).
17.	5h. 39m.	Uranus in conjunction with the Moon. (Uranus 3° 0′ N.).
22.	10h. 11m.	Mars in conjunction with the Moon. (Mars 4° 26′ N.).
23.	13h. 15m.	Venus in conjunction with Uranus. (Venus 2° 33′ S.).
,,	14h. 53m.	Saturn in conjunction with the Moon. (Saturn 1° 32′ N.).
,,	7h. 39m.	Minimum of Algol (β Persei).
26.	20h. 55m.	Eclipse of the Moon, partly visible at Greenwich.
,,	4h. 28m.	Minimum of Algol.
29.	23h. 22m.	Neptune in conjunction with the Moon. (Neptune 4° 14′ S.)

RE-DISCOVERY OF WINNECKE'S COMET (1909*d*).—A telegram from the Kiel Centralstelle announces that Winnecke's comet was re-discovered at the La Plata Observatory, Argentina, on October 31. Its position on that date at 8h. 14·1m. (La Plata M.T.) was 17h. 11m. 51·6s., −27° 18′ 43″, and its magnitude was about 10·0; this position lies a little to the south-west of θ Ophiuchi. According to Prof. Hillebrand's elements, the perihelion passage took place on October 4·0 (G.M.T.).

HALLEY'S COMET.—According to a note in the November number of the *Observatory*, Halley's comet is steadily increasing in brightness, and ten minutes' exposure, presumably with the Greenwich 30-inch reflector, gives a strong image. Reproductions of photographs are given in the *Observatory* (Greenwich, September 23), *Knowledge*, and the *Astrophysical Journal* (Yerkes Observatory, September 16, 17, 24, and 26). The *Observatory* (No. 415, p. 435) also gives an ephemeris for April and May, 1910, the time of perihelion passage being taken as April 19·65

G.M.T. From this we see that the nearest approach to the earth should occur on May 20, the distance then being 14·3 million miles. The revised elements indicate that the comet should transit the sun's disc on May 18d. 14h., but the transit will, of course, be invisible in Europe. It appears possible that, at that time, the comet's tail may extend beyond the earth and be visible in the midnight sky.

From observations made with the 40-inch Yerkes telescope Prof. Barnard concludes that the comet is brightening rapidly, and was not fainter than magnitude 13·5 on October 17–19; the diameter was estimated at 15″, the comet being a little brighter towards the centre.

The Astronomischen Gesellschaft prize has now been definitely awarded (*Astronomische Nachrichten*, No. 4366) to Messrs. Cowell and Crommelin.

SATURN.—A telegram from the Flagstaff Observatory announces that the lacings crossing Saturn's equatorial bright belt, detected at that observatory, have now been photographed there (Circular No. 114, Kiel Centralstelle).

MERCURY.—From the careful study of some twenty photographs, taken at the Massegros Observatory during the elongation of September last, M. Jarry-Desloges arrives at the conclusion that the rotation period of Mercury coincides with the period of revolution. The photographs show a number of details (*Astronomische Nachrichten*, No. 4366, p. 375, November 1).

THE "FLASH" SPECTRUM WITHOUT AN ECLIPSE.—Yet another important development in solar spectroscopy emanates from Mount Wilson, Messrs. Hale and Adams, in No. 3, vol. xxx., of the *Astrophysical Journal*, describing the apparatus and method whereby they have succeeded in photographing the bright-line spectrum of the lower chromosphere without waiting for a total eclipse. With their apparatus such photographs may now be obtained at any time when the sun is observable.

After describing the previous attempts to attain this end, made at Kenwood, Yerkes, and Meudon, they give a brief description of the additions to the 30-foot spectrograph which enabled them to accomplish it.

The main difficulty in such photography is to keep the solar image exactly tangential to the slit, but they have overcome this by fitting a slipping-plate over the slit-plate. This slipping-plate is moved, parallel to the slit-plate, by a fine screw, and carries a right-angled prism which reflects the image of the limb on to a second, similar, prism fixed in front of the slit so as to reflect the rays between the slit jaws. The observer watches the spectrum, and by moving the slipping-plate preserves the tangential position, which gives the "flash" spectrum, throughout the exposure. The tower telescope gives a solar image of 6·7 inches diameter, and a grating having 568 lines per mm. on a ruled surface 49 mm. by 82 mm. is employed; better results are anticipated when the new 150-foot tower telescope becomes available. At present provisional wave-lengths are given for 124 "flash" lines, which are tabulated to show coincidences with Rowland's solar lines and with the eclipse lines observed by Evershed, Frost, Jewell, and Lockyer, respectively. The deviation of the wave-lengths of these lines from those given by Rowland for the corresponding solar lines is less than the probable error of measurement; if the bright lines of the "flash" spectrum were due to anomalous refraction at the sun's edge, as suggested by Julius, the two sets of wave-lengths should differ considerably.

SEARCH-EPHEMERIS FOR GIACOBINI'S COMET, 1896 V.—A revised set of elements for the comet discovered by Giacobini on September 4, 1896, is published by that observer in No. 4364 of the *Astronomische Nachrichten*, and gives the probable date of perihelion passage as December 19, 1909.

Three search-ephemerides are also given, one assuming that perihelion will occur on December 19·364, the others for ten days before and after, respectively. The position for November 4 is $\alpha = 18\text{h. } 13 \cdot 1\text{m.}$, $\delta = 15° \ 1'$ S., and the brightness is given as 0·58, unity being about equivalent to magnitude 12·0. The southerly declination and comparative faintness of the object render it unlikely that the comet will be observable, if found, except by the largest instruments.

THE UPPER AIR.[1]

THE past decade has been very fruitful in the investigation of the upper air. By the use of kites sufficient results have been obtained to furnish a tolerably complete knowledge of the variation in the meteorological elements up to a height of 2 km., while registering balloons have furnished information regarding the distribution of temperature up to heights of 15–20 km. The results of the Berlin manned balloon ascents were arranged and discussed very fully ten years ago, but no such comprehensive discussion of the much more numerous kite and registering balloon ascents has yet been attempted. The present report deals with the instruments and methods of investigation, and with the results for temperature and for wind.

The most important series of the earlier ascents with manned balloons was that made by Glaisher in 1860–70. Unfortunately, he was led to believe that artificial ventilation of the thermometers was unnecessary, with the result that his observations at great altitudes are untrustworthy. In the series of ascents made from Berlin in 1888–95, observations made with careful ventilation proved beyond doubt that large errors would arise in the absence of proper ventilation, and that Glaisher's results were almost certainly affected by such errors.

The following table shows the nature of the errors, and incidentally furnishes a comparison with one of the earlier *ballon-sonde* ascents :—

Height, metres	Fall of temperature ° C. per 1000 metres		July 31, 1901	
	Glaisher	Berson	Berson and Süring	Ballon-sonde
0–1000	7·5	5·0	7·2	8·3
1000–2000	6·5	5·0	6·8	6·1
2000–3000	5·0	5·4	3·7	4·2
3000–4000	4·2	5·3	5·2	5·1
4000–5000	3·8	6·4	7·4	5·7
5000–6000	3·2	6·9	5·5	6·3
6000–7000	3·0	6·6	7·2	4·7
7000–8000	2·0	7·0	7·2	7·6
8000–9000	1·8	9·0	3·6	7·1

Temperature observations in manned balloons are now usually taken with an Assmann's aspirator, in which a ventilating current of about 4 m.p.s. is forced by a fan through a polished tube containing the thermometer and screening it from radiation.

The instruments used with registering balloons are of two types. In the large type the record is made on a metal or photographic sheet, covered with lamp-black, and wrapped round a revolving cylinder driven by a clock. Pressure, temperature, and humidity are recorded by separate pens. The barometer is a Bourdon tube or an aneroid, the thermometer some form of bimetallic instrument, and the hygrometer a bundle of hairs. In the small type the temperature record is traced on a cylinder or plate, which is itself moved at right angles to the direction of motion of the temperature lever by the changes of pressure. The temperature and pressure are then given by the ordinates and abscissæ of the trace obtained. The advantage of this arrangement is that no clock is required, and the instrument can be made much lighter and is more easily tested. The loss of the humidity trace is unimportant, because the hygrometric records at low temperatures are very untrustworthy, and the observations in the lower layers can be made with kites or manned balloons.

The instruments used with kites are similar to the *ballon-sonde* instruments of the larger type, but they have an arrangement for recording wind velocity. In the Dines instrument the records are traced on a flat, circular sheet of cardboard rotated by means of a clock and resting on a wooden tray beneath which the instruments are placed.

The *ballon-sonde* instruments are tested either (1) by keeping the thermometer at ordinary atmospheric pressure in testing for temperature, and the barometer at ordinary temperatures in testing for pressure, or (2) by testing the thermometer through the temperature range at different pressures and the barometer through the pressure range at different temperatures. The second is, of course, the more desirable plan, but the difficulties involved in applying it to the larger type of instrument are so considerable that the former method is generally adopted where such instruments are used. The simplicity of the smaller type of instrument devised by Dines enables the second method to be adopted in testing it, without elaborate and expensive apparatus.

---

[1] Report on the Present State of our Knowledge of the Upper Atmosphere as obtained by the use of Kites, Balloons, and Pilot Balloons." Report of the Committee, consisting of Messrs. E. Gold and W. A. Harwood, presented at the Winnipeg meeting of the British Association, 1909.

Temperature records obtained simultaneously with different instruments show differences which, in the mean, do not exceed 1° C., and the temperatures may, in general, be taken to be correct to this degree of accuracy, but lagging of the instruments makes it doubtful if in all cases the recorded temperatures and heights actually correspond.

In dealing with the observations, it is found convenient to express temperatures in degrees C. above the absolute zero, −273° C. on the ordinary scale. Where necessary the letter A is used to characterise this scale. Atmospheric temperatures, both at the surface and in the upper air, lie almost always between 200° A and 300° A, so that the 2 may be dropped without risk of confusion. Gradients of temperature are expressed in degrees C. per km., and are reckoned + when temperature decreases upwards.

The mean value of the gradient up to 3 km. is as follows:—

	°
From the Berlin manned balloon ascents, 1888–1897	5·1
,, ,, ,, .. 1897–1907	4·8
,, Berlin and Lindenberg kite ascents	4·7
Calculated by Hann from mountain observations	5·7

It follows from these results that the mountains are colder than the free atmosphere at the same height, and many observers have verified this fact by direct comparison. Shaw and Dines found that in July, 1902, the temperature on Ben Nevis was 2·6° C. below that of the free atmosphere at the same height to the west of the mountain. Schmauss found that the temperature on Zugspitze (nearly 3000 m.), which lies on the northern edge of a mountainous region, was continually lower than that of the free atmosphere, but was higher than that at the same height on Sonnblick, which lies in the middle of the Alps.

It was pointed out by Von Bezold that increase of temperature on a mountain is limited by convection, whereas no immediate limit is set in this way to cooling. There is a one-sidedness in the heat exchange between the mountain surface and the atmosphere which would tend to produce the result found by observation. Moreover, convection always tends to raise the temperature of the upper air above what it would be otherwise, and, in addition, the cold of winter is, as it were, stored up in the snow, while no such process holds for the warmth of summer. Both conditions are probably effective in increasing the temperature difference. The most important deduction to be made from the results is that the mountains are not cold because the upper air is cooled by convection, but they are cooled by their radiation to space.

The mean values of the gradients up to 15 km., found from registering balloon ascents at ten European stations and for St. Louis, U.S.A., are given in the table:—

Height		0–1	1–2	2–3	3–4	4–5	5–6	6–7	7–8 km.
Gradient	Europe	3·6	4·3	5·2	5·8	6·3	6·8	7·2	7·4
	St. Louis	5·1	5·3	4·7	5·2	5·9	6·2	[illegible]	[illegible]

Height		8–9	9–10	10–11	11–12	12–13	13–14	14–15 km.
Gradient	Europe	6·8	5·0	3·3	0·7	−0·8	0·0	−0·1
	St. Louis ...	7·4	6·7	5·5	2·9	1·4	0·6	−0·9

The maximum value occurs in the layer 7–8 km., and its magnitude indicates that the effect of radiation is to leave practically unchanged the natural gradient in air in vertical motion. Gold showed that in the upper layers absorption exceeded radiation, and in the lower layers radiation exceeded absorption, and both processes would diminish the temperature gradient. At an intermediate stage absorption and radiation must balance, and the results indicate that this is the case at a height of 7–8 km. The temperature at different heights up to 15 km. shows practically no variation for the ten European stations except in the case of Pavlovsk, where the temperature is uniformly lower up to 10 km. and higher above 10 km. than at the other stations. The difference of temperature between Strassburg and Pavlovsk, taken to represent lat. 50° and lat. 60° respectively, is sufficient to produce a gradient of pressure at a height of 10 km. which would correspond to a steady west wind of about 24 m.p.s. (54 miles per hour). The difference between Strassburg and St. Louis (representing lat. 39°) would at the same height correspond to a steady west wind of 15 m.p.s. in intermediate latitudes. The observations are not sufficiently extensive to warrant much stress being laid on the absolute values of these velocities, but it is of interest to note that the approximate ratio of the west winds in lats. 45°, 55°, deduced from Oberbeck's solution by a purely theoretical treatment of the problem of the general circulation, is 16/21 for the upper strata, a result in tolerable agreement with the ratio 15/24 deduced from the temperature observations.

The problem of the vertical distribution of temperature in cyclones and anticyclones depends for its solution on upper-air observations. Hann deduced from the temperatures at high-level observatories that cyclones were colder than anticyclones, the mean difference of temperature up to 3·5 km. being as much as 5° C. Grenander found similar results by a consideration of the kite and balloon ascents at Hald and Berlin, while Von Bezold deduced from the Berlin manned balloon ascents that the relative coldness of the cyclone was maintained even up to 8 km.

The results in the present report, obtained by taking only those cases in which the sea-level pressure exceeded 770 mm. or was less than 750 mm., and correcting the observations for seasonal and local variations, showed that the cyclone was colder than the anticyclone up to 9 km., while at greater heights the conditions were reversed, and the anticyclone became much colder than the cyclone; but the effect of the temperature difference in the lower layers on the pressure difference is so considerable that even at 14 km. the pressure gradient is not reversed. In these circumstances it is difficult to see how air can be brought into the anticyclonic and out of the cyclonic regions in the upper air. The cirrus observations imply a definite outward motion over cyclonic regions, but a rotation in the same direction as at the surface, which can be the case only if the gradient of pressure is also in the same direction as at the surface. These results imply that there is motion across the isobars from the lower to the higher pressure. Now, although it is possible for such motion to exist if the velocity in the cyclonic region exceeds a certain value, or, in the anticyclonic region, lies between certain limits, it is not possible to have steady motion of this type, and the effect of damping would be to make the motion from the higher to the lower pressure. The evidence points to the conclusion either (1) that cyclones and anticyclones arriving in the European area are in general dissipating systems which are continually replaced by other systems arriving from what may be called productive regions, or (2) that there is interchange of air with regions in which the surface temperature or the temperature gradient differs sufficiently to produce mean temperatures greater in low-pressure areas and less in high-pressure areas than are found over Europe.

It is interesting in connection with this part of the subject to note that Shaw and Lempfert deduced from a discussion of surface air currents that the central areas of anticyclones were not the regions of origin of currents, and could not, therefore, be places where descent of air was taking place to any considerable extent. The temperature observations in the first 3 km. agree with this conclusion, since they show that there is no approach to a regular adiabatic gradient near the centres of anticyclones.

Perhaps the most remarkable phenomenon revealed by the observations from registering balloons is the comparatively sudden cessation of the fall of temperature at a height which varies from day to day, but is roughly equal to 10 km. Above this height, which may be regarded as the height of an irregular, but roughly horizontal, surface dividing the atmosphere into two regions, the temperature at any time varies very little in a vertical direction, showing, on the average, a slight tendency to increase. The lower and upper regions are characterised by the terms "convective" and "advective" respectively, and the height and temperature of the dividing surface are denoted by H_c and T_c. The following table gives the values of H_c, T_c, for certain places in Europe:—

	Mean of 13 Stations	Munich	England	Strassburg	Paris	Pavlovsk	Koutchino	Milan	Vienna	Berlin
H_c	10·6	10·9	10·8	10·8	10·4	9·6	10·6	10·7	10·2	10·7
T_c	16°	16°	18°	15°	18°	18°	14°	17°	15°	16°
No. of cases ...	336	53	32	67	57	28	18	25	24	32
Latitude... ...	—	48°	52°	49°	49°	60°	56°	45°	48°	52°

There is very little variation for places between lat. 45° and lat. 55°, but at Pavlovsk H_c is about 1 km. below the average. Observations made in the equatorial regions show that the value of H_c there exceeds 15 km., so that there must be a considerable increase in its value in crossing the limit of the trade-wind region, and it appears probable that the equatorial currents and the trade winds form a closed system with little interchange of air with higher latitudes.

The annual variation in H_c, T_c is shown by the following table:—

Annual Variation in H_c.

	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Mean of 13 stations...	10·3	10·4	9·1	10·1	10·5	10·7	10·9	11·4	10·4	11·9	10·8	10·1
Number of cases ...	26	22	32	39	31	27	24	61	46	38	25	25
Munich	10·0	10·4	9·2	9·2	11·2	11·0	11·7	12·0	10·3	12·3	11·8	11·4
Number of cases ...	4	3	6	4	2	4	3	11	5	5	2	5
Strassburg...	10·5	10·6	9·4	9·4	10·6	10·9	10·8	12·3	[illegible]	11·9	11·0	[illegible]
Number of cases ...	5	5	5	5	4	5	4	9	8	6	6	[illegible]

Annual Variation in T_c.

	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Mean of 13 stations...	13	11	16	16	17	20	20	18	22	14	15	14
Munich	14	10	16	19	25	20	15	16	26	9	10	13
Strassburg...	11	10	16	20	17	17	21	15	23	13	12	10

The remarkable feature is the relatively high temperature and low value of H_c in March and September. This peculiarity and the fact that T_c is least near the equator suggest that the general nature of the process may be as follows. The cool air above the equator moves polewards, and in the natural course descends again to feed the trade winds. Owing to the irregularities of the earth's surface, the change of seasons and the very considerable difference between the northern and southern hemispheres, the process will be neither regular nor symmetrical. Consequently, the equatorial cold air will encroach on the advective region of temperate latitudes, and such encroachments will produce anticyclonic regions. The advective atmosphere would be reached there at a higher level, and initially at a lower temperature than in the average state, but the temperature would be gradually raised by absorption of thermal radiation to the normal value for that latitude.

The fact that H_c has minimum values in March and September, when equatorial temperatures are highest, appears at first to be contrary to this view; but the first effect of increased temperature will be to increase the strength of the trade winds, and as at the same time there is a transference of air across the equator to the southern hemisphere, a transference which can be made only through the upper return current, there will be a deficiency of descending air, and the equatorial cold air will encroach less than usual on the northern advective region. The reverse process would be expected to occur in September, but the autumnal transference of air to the northern hemisphere will be initially much more intense towards the great continental regions than to the Atlantic and European area, and it may well be that the equatorial current again encroaches less than usual on that region. It may be expected that the value of H_c in Asia and America will not show the September minimum.

The explanation of the discontinuity in the temperature gradient appears to be this. The fall of temperature is governed mainly by convection, and a necessary condition for convection to persist is that the radiation shall exceed the absorption in the upper layers of the convective system. A limit is therefore set to the height to which convection can extend, and at this limit the discontinuity in the fall of temperature occurs. It has been shown that the observed height is about the same as the limiting height of the convective system found from theoretical considerations based on the experimental knowledge of the radiating power of the atmosphere.

The results of the observations of wind velocity may be briefly summarised as follows. In general, the velocity increases with height, the greater part of the increase up to 2000 m. taking place in the layers immediately above the surface; 75 per cent. of the total increase takes place in the first 160 m. Above 500 m. numerous cases occur where the velocity decreases with height. The velocity for heights up to 10 km. is given approximately by the equation $V\rho = V_0\rho_0$ (Egnell's law), where V is velocity and ρ density, $V_0\rho_0$ being the values near the surface. The law implies that the pressure gradient remains constant and independent of the height. Now, owing to the fact that the temperature is higher over regions of high pressure than over regions of low pressure, the ratio of pressure gradient to density increases with height. The condition for a constant gradient up to 8 km. is approximately

$$t_0 = \frac{74\,\delta p}{p} \text{ degrees C.},$$

where t_0 is the excess of the mean temperature of the air-column at a place at pressure $p+\delta p$ above that at a place at pressure p. Observations show that for $\delta p = 20$ mm., $t_0 = 4°$ C. nearly, or double the amount necessary for constant gradient. It is to be expected, therefore, that $V\rho$ will increase up to 8 km., and the few pilot-balloon observations available point to such an increase.

The direction of the upper wind usually veers from that at the surface. The following table shows the deviations for winds from different quadrants in England and at Berlin:—

Deviation of the Upper Wind.

England.

Heights	0·5 km.	1·0 km.	1·5 km.	2·0 km.	2·5 km.	3·0 km.
W. ...	9°	14°	14·5°	14°	8°	8°
N. ...	4	8	3	−1	−3	−15
E. ...	15	22	20	28	35	21
S. ...	14	26	32	38	41	50

Berlin.

Heights	0·5 km.	1·0 km.	1·5 km.	2·0 km.	2·5 km.	3·0 km.
W. ...	18°	23°	23°	20°	23°	22°
N. ...	13	17	20	20	15	25
E. ...	27	30	38	45	46	44
S. ...	38	46	48	49	53	46

The deviation at Berlin is in nearly all cases greater than in England, especially for north winds, which back slightly in the upper air in England.

There is no marked difference between anticyclonic and cyclonic conditions in the change of wind velocity and direction with height. The following table gives the values deduced from observations at Berlin and Lindenberg in 1905:—

	Height	Surface	1 km.	2 km.
Anticyclonic (A)	Deviation ...	—	30°	33°
	Velocity	4·1	8·2	8·4 m.p.s.
	Ratio to surface velocity	1·0	2·0	2·05
Cyclonic (C)	Deviation ...	—	30°	37°
	Velocity	5·9	10·5	10·7
	Ratio to surface velocity	1·0	1·78	1·82

The deviation is slightly greater and the ratio slightly less in C than in A. It would be natural to suppose that surface friction and irregularities would produce a decrease in velocity which increased at a greater rate than the velocity itself, and in that case the ratio in C would be greater than in A, as was actually found by Berson from the manned balloon observations.

SOLAR VORTICES AND MAGNETIC FIELDS.[1]

II.

I HAVE already referred to the importance of applying in astronomical research the methods of the physicist. During the last quarter of a century the study of spectroscopic phenomena in the laboratory has been completely transformed. It may well be said that this transformation, which has involved such discoveries as spectral series, the effect of pressure on wave-length, and the Zeeman effect, has been directly due to the use of Rowland's concave gratings, of great focal length, arranged for photography. In astronomical spectroscopy great advances have also been made, but the spectroscope has continued to occupy the place it formerly held as an attachment of the telescope. Although Rowland used a long-focus concave grating for his classic study of the solar spectrum, the heliostat and lens employed with this instrument gave so small a solar image on the slit that the investigation of sun-spots and other details was impossible. We thus see that while in the observatory the spectroscope continued to be used as an accessory of the telescope, in the laboratory the parts were exchanged and the telescope was employed simply as an accessory of the spectroscope. It seemed obvious that a great opportunity for advance lay open to the investigator who would combine a long-focus spectroscope with a long-focus telescope. As it would be difficult, or perhaps impossible, to use for photography a sufficiently long spectroscope attached to the tube of an equatorially mounted telescope, some form of fixed telescope was plainly essential.

The tower telescope on Mount Wilson (Fig. 5) is designed to accomplish this purpose. It consists essentially of a 12-inch refracting telescope, of 60-feet focal length, mounted in a fixed position, pointed directly at the zenith. The ordinary telescope tube is replaced in this case by a light steel tower, firmly held in position by steel guy ropes. The 12-inch objective lies horizontally at the summit of the tower, and sunlight is reflected into it from the second of two adjustable plane mirrors. The first of these mirrors is mounted as a cœlostat, and is rotated by an accurate driving-clock about a polar axis at such a rate as to counteract the apparent motion of the sun. Thus a beam of sunlight is reflected from the cœlostat mirror to the second mirror, which sends it vertically downward through the objective. In the focal plane, 60 feet below the objective, an image of the sun, about 6·6 inches in diameter, is formed on the slit of a spectrograph, at a height of about 3 feet above the surface of the ground. After passing through the slit, the light of any desired portion of the solar image (a sun-spot, for example) descends vertically into a well about 30 feet deep excavated in the earth beneath the tower. Thirty feet from the slit the diverging rays encounter a 6-inch objective, through which they pass. After being rendered parallel by the objective, the rays fall upon a Rowland plane grating, ruled with 14,438 lines to the inch. The grating breaks up the light into a series of spectra, and the rays are returned through the same objective, which brings the spectra to a focus at a point near the slit. By inclining the grating at a small angle, the image of the spectrum is made to fall at a point slightly to one side of the slit, and here the photographic plate is placed. Thus a portion of the spectrum 17 inches in length can be photographed in a single operation. In the work on sun-spots, most of the photographs are taken in the third order of the grating, where the dispersion and resolving power are very high. When the spot spectrum is being photographed, only the light from the umbra is admitted to the slit. At the end of the exposure this portion of the slit is covered, and light from the photosphere, at a point removed from the spot, is admitted to the slit on either side. Thus the narrow spot spectrum is photographed between two strips of solar spectrum, used for comparison.

The advantages of this combined form of telescope and spectrograph are considerable. On account of the great thickness (12 inches) of the mirrors, the height of the cœlostat above the heated earth, and the use of a vertical beam, the definition of the solar image is always better than with the Snow (horizontal) telescope. Another important advantage is the nearly constant temperature at the bottom of the well, where the grating is placed. This permits long exposures to be given, when necessary, without danger of such displacements of the spectral lines as would be caused by expansion or contraction of the grating. The grating used in this spectrograph is a small one, which I have employed in most of my work since 1889, but the unusual focal length of the spectrograph permits the full visual resolution of the grating to be utilised in photographic observations. Thus it has become possible to photograph the widened lines and doublets, as well as a host of narrow lines, most of them due to chemical compounds, which had not previously been recorded in the spot spectrum.

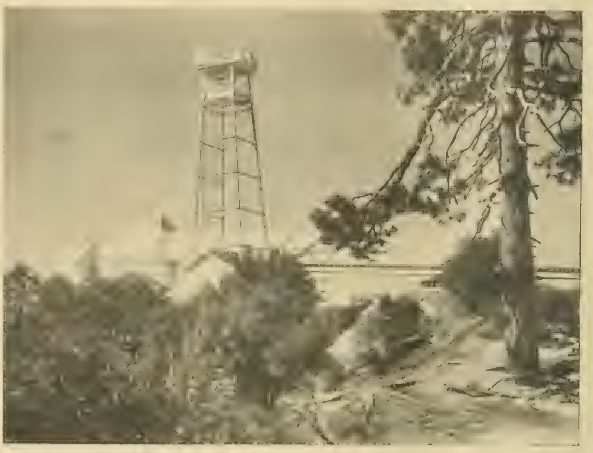

FIG. 5.—Tower Telescope on Mount Wilson.

Lack of time prevents me from discussing in this lecture the various studies of sun-spot lines carried out with this instrument before the attempt to detect a magnetic field in spots was undertaken. An extensive catalogue of these lines is nearly complete, a preliminary map has been issued and a better one is in preparation, and a series of investigations with the arc and electric furnace has suggested that the strengthening and weakening of certain lines is due to a reduction in the temperature of the spot vapours. At present we are concerned with the cause of the widening and doubling of spot lines, and the method of testing this question must now be described.

A Nicol prism was mounted above the slit of the spectrograph, and just above this a Fresnel rhomb. If the components of a spot doublet were circularly polarised in opposite directions, passage through the rhomb should give two plane polarised beams, the planes of polarisation making an angle of 90° with each other. Thus in one position of the Nicol one of the components should be photographed alone, and by turning the Nicol 90° this should disappear and the other component come into view.

When this test was applied with the tower telescope, in June, 1908, the true character of the spot doublets became apparent (Fig. 6). One or the other component of the doublet could be cut off at will by rotating the Nicol, precisely as Zeeman had done in the laboratory. On account of the unique character of the Zeeman doublets, this test alone was almost sufficient to prove the existence of a magnetic field in sun-spots. But one of the great beauties of the Zeeman effect is its many-sided character, which permitted the test to be multiplied and extended. From Zeeman's first experiments it was known, for example, that if the strength of the magnetic field is insufficient to separate completely the components of a doublet, the edges of the resulting widened line should be circularly polarised in opposite directions. Thus those lines which are widened, but not doubled, in spots might be expected to shift in position when the Nicol is rotated. This was found to be the case. Again, the lines which constitute the flutings of the spectra of compounds are not, in general, affected by a magnetic field. Hence such lines in the spectrum of a sun-spot should not be shifted when the Nicol is rotated. This, also, was found to be true. But a still more satisfactory test was suggested by another laboratory phenomenon. When a doublet is observed along the lines of force, with one of the components extinguished by the Nicol, reversal of the current through the magnet should extinguish the visible component and cause the invisible one to appear. In the sun, according to our hypothesis, reversal of the direction of revolution in a vortex should correspond to reversal of the current through the coils of a magnet. Hence the red component of a doublet should appear in the spectrum of a vortex rotating in one direction, the violet component in that of a vortex rotating in the reverse direction. Fortunately, the appearance, on opposite sides of the solar equator, of two spot vortices rotating in opposite directions (Fig. 4) made this test possible. The results were perfectly in accord with the hypothesis.

---

[1] Discourse delivered at the Royal Institution on Friday, May 14, by Prof. George E. Hale, For.Mem.R.S. Continued from p. 23.

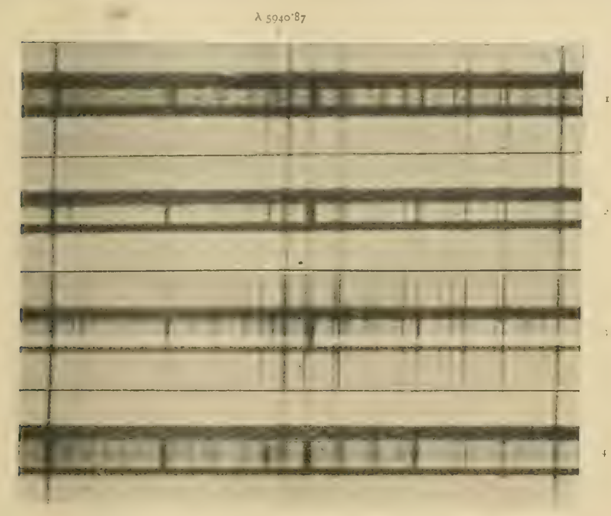

Fig. 6—(1) Southern Spot, showing Red Components of Doublets. Nicol, 29° W. (2) Northern Spot, showing Violet Components of Doublets. Nicol, 29° W. (3) Northern Spot, showing Red Components of Doublets. Nicol, 61° E. (4) Spot Spectrum without Rhomb or Nicol, showing both Components of Doublets.

So far we have been considering only such phenomena as are observed parallel to the lines of force of a magnetic field; but a spectral line which, in such circumstances, appears as a doublet is usually transformed into a triplet when the observation is made at right angles to the lines of force. The circularly polarised side components of the doublet give place to plane polarised components, occupying the same position, while another line appears centrally between them. The light of this line is also plane polarised, the direction of the vibrations being parallel to the field, while the vibrations of the side components are in a plane at right angles to the field. Thus when a spot is carried by the solar rotation to a point near the limb we might expect the double lines in its spectrum to be transformed into triplets if produced by a magnetic field. The failure of the central line to appear seemed to raise an important argument against the magnetic hypothesis.

At this point the necessity of conducting laboratory investigations in immediate conjunction with astronomical observations is well illustrated. Fortunately, our laboratory was already well equipped for work of this nature (Fig. 7). In anticipation of the possibility that observations of the Zeeman effect would be needed in the interpretation of solar and stellar phenomena, a powerful electromagnet, with suitable accessory apparatus, had been provided. A brilliant spark, produced between metallic electrodes in the field of the magnet, furnished the source of light. As many of the double lines in sun-spot spectra are due to iron, this metal was selected for the first experiments. The spectrum was photographed, at various angles with the lines of force, with a powerful spectrograph, like the one used with the tower telescope, similarly mounted in an underground chamber.

The difficulty of accounting for the behaviour of the iron doublets in the sun was removed by these investigations. It appears that these lines do not become triplets when observed across the lines of force. In reality they are changed to quadruplets, or doublets in which each of the components is a close double line. In the magnetic field of sun-spots, which is much weaker than the field used in the laboratory, the closely adjoining lines which constitute the components of the doublets cannot be separated. Thus these sun-spot lines should appear double at whatever position the spot may occupy on the sun's surface.

The distance between the components of doublets or triplets separated in the magnetic field varies greatly for different lines. Some exceptional lines are not affected in the least, others are merely widened, and others are clearly and sometimes greatly separated. It is therefore important to compare the widening and the separation of lines in a sun-spot spectrum with the corresponding phenomena in the magnetic field. With few exceptions, most of which may be accounted for by the presence in the spot spectrum of closely adjoining lines of other elements, the solar and laboratory results were found to be in good agreement. The following table gives a comparison of certain iron lines in the spot and laboratory :—

Wave-length	Δλ, spark	$\frac{\Delta\lambda, \text{spark}}{5\cdot1}$	Δλ, spot	
6213·14	0·703	0·138	0·136	−0·002
6301·72	0·737	0·144	0·138	−0·006
6302·71	1·230	0·241	0·252	+0·011
6337·05	0·895	0·175	0·172	−0·003

The column headed "Δλ, Spark" gives the distance between the components of the lines as observed in the laboratory. As the strength of the magnetic field used in the laboratory was about 5·1 times that of the spot, the quantities obtained by dividing the separations in the second column by 5·1 are given in the third column. These separations are directly comparable with the separations of the corresponding lines in the spot, which are given in the fourth column. The fifth column shows that the differences between the solar and laboratory results are very small. As the strength of the field in the laboratory was about 15,000 gausses, the strength of the field in this spot would be about 15,000÷5·1=2900 gausses. The strongest field hitherto measured on our photographs of spot spectra is about 4500 gausses, corresponding to a considerably greater separation of the lines (Fig. 8).

When a similar comparison was made for various lines of titanium and chromium, a much less perfect agreement between the spot and laboratory results was found. It had already been observed that such lines as D of sodium and *b* of magnesium, which undoubtedly represent a much higher level than the great majority of lines in the spot spectrum, are but very slightly widened. As these lines are strongly affected by a magnetic field in the laboratory, it appeared evident that the strength of the field in spots must fall off rapidly in passing outward through the spot vapours. In these circumstances lines of other elements, which represent levels higher than the average, should show small separations in the magnetic field of the spot. It seems probable that in this way the lack of perfect agreement between the laboratory and solar results observed in the case of titanium and chromium can be accounted for.

A further important test was afforded by the well-known phenomenon exemplified in Preston's law. According to this law, the distance between the components of the lines split up by a magnetic field varies directly as the square of the wave-length. This we found to be true even in the case of a metal like iron, the lines of which cannot be grouped into series, if the average separations of a sufficient number of lines were considered. We should therefore expect that the widening of lines in spots would rapidly decrease toward the violet, and that the separation of spot doublets should diminish in a similar way. A study of the spot spectrum shows that this actually occurs.

It soon appeared that the normal spot spectrum always contains triplets as well as doublets (Fig. 8). These are less easily recognised, because the presence of the central line crowds the components so closely together that they are not readily separated with the resolving power available. As these triplets are photographed even when the spot is very near the middle of the sun, it is evident that the spot always sends out light which makes a considerable angle with the lines of force. In a normal triplet the central line is of twice the intensity of the side components, when observed at right angles to the lines of force, and disappears altogether when observed parallel to the lines of force. Thus, by determining the relative intensities of the central and side lines of such a triplet, the angle between the lines of force and the line of vision can be obtained. In the case of sun-spots, the data at present available are not sufficient for the accurate determination of this angle, but it seems to lie between 30° and 60° when the spot is near the centre of the sun. On the hypothesis that the magnetic field is produced by the spot vortex, it would then follow that the axis of the vortex, instead of being radial, as we at first assumed, makes an angle of much less than 90° with the surface of the photosphere.

The time at my disposal permits me to describe briefly only a few other phases of this investigation. In the laboratory the central line of triplets is polarised in a plane parallel to the magnetic field. Hence, if the light is passed through a Nicol prism, used without a rhomb, it should be possible to extinguish this line at certain positions of the Nicol, in which case a spot triplet would appear as a doublet. This test has also been applied to the spot triplets, with the expected result. In fact, this method supplies a convenient means of recognising close triplets, the components of which are too closely crowded to be seen separately before the central line is cut out. Indications have also been obtained of what may prove to be unequal rotation of the plane of polarisation of this central line in different parts of spots. The gradual decrease in the strength of the field from the umbra to the outer limit of the penumbra has been studied, and magnetic fields have been detected on the sun's disc, in certain regions outside of sun-spots. It is evident that many new phases of the subject are likely to be developed in the future, especially if larger images of the sun and more powerful spectrographs are employed. In this connection it may be stated that a tower telescope of 150-feet focal length, to be used on Mount Wilson with a spectrograph of 75-feet focal length, is now under construction.

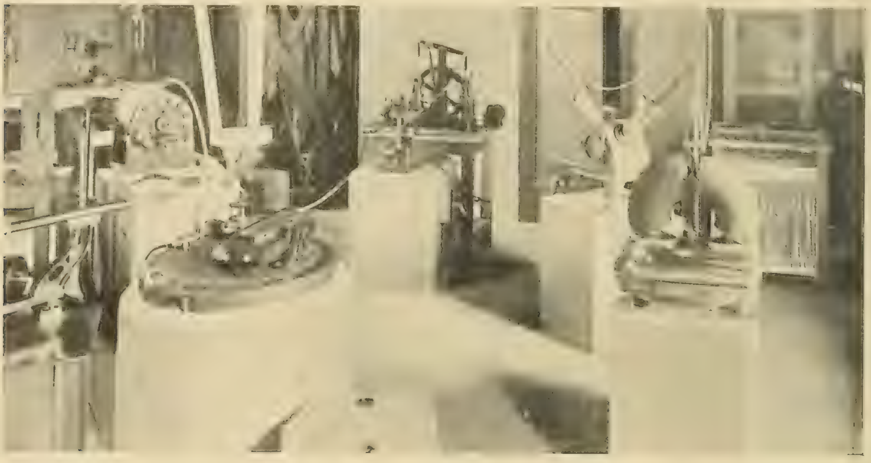

FIG. 7.—Interior of Pasadena Laboratory, showing Slit-end of Vertical Spectrograph and Magnet used in study of Zeeman effect.

This will give a focal image of the sun about 16 inches in diameter, in which small spots, as well as large ones, can be studied.

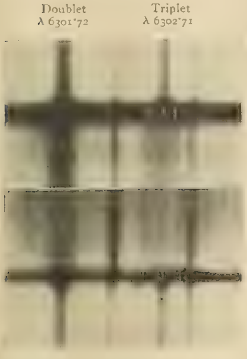

FIG. 8.—Iron Doublet (λ 6301·72) and Triplet (λ 6302·71) in Two Spot Spectra, showing Field Strengths of 2900 and 4500 Gausses respectively.

Although it now seems to be demonstrated that sun-spots are electric vortices, judgment should be reserved as to the various theories which have been advanced to account for their origin. Many of the results I have described appear favourable to Emden's solar theory, but it seems to be opposed by the important investigations of Evershed, who has found that the metallic vapours in sun-spots flow radially outward from the umbra, parallel to the photosphere. The further development of Evershed's work, and the continued study of solar vortices and magnetic fields, should soon permit a trustworthy theory of sun-spots to be formulated.

It is evident that the rapid decrease upward of the strength of the field in spots would prevent this field from having an appreciable influence on the higher solar atmosphere. At the distance of the earth, as Schuster has shown, the combined magnetic effect of several spots, all assumed to be of the same polarity, and having no such rapid decrease in field strength at higher levels as is actually observed, would be altogether incompetent to account for terrestrial magnetic storms.

In concluding, I wish to express my appreciation of the assistance I have received from my colleagues at Mount Wilson. I am particularly indebted to Messrs. Adams, Ellerman, King, Nichols, and St. John for aid in connection with the present investigation.

THE NEW ROOMS OF THE ROYAL SOCIETY OF EDINBURGH.

ON Monday, November 8, the new rooms of the Royal Society of Edinburgh were formally opened by an appropriate inaugural address from the president, Sir William Turner, followed by a brilliant reception. For the purposes of the reception the ordinary meeting-room was transformed into the cloak-room, and the president's address was delivered in the Freemasons' Hall, a few blocks further west in George Street. After the address the audience re-assembled in the society's new abode, and had every opportunity of inspecting the arrangements which had been made for the accommodation of the large and growing library and for other possessions of the society.

The important events which led up to the migration of the society from its historic haunts in the beautiful building in Princes Street were described by the president in his address. The National Galleries of Scotland Bill, introduced into the House of Commons in 1906, provided that the Royal Institution, so long the home of the society, should form a part of the National Gallery of Scotland and be applied to the promotion of the Fine Arts. As the result of representations made by the society, a clause was introduced into the Bill by which the Treasury was empowered to provide funds both for the purchase and equipment of a new habitation for the society, and for an annual grant of 600*l.* to assist in the discharge of the scientific work. The natural feeling of regret at having had to give up one of the finest sites to be found in any city of the world is partly balanced by the knowledge that now the society has, for the first time in forty or fifty years, ample accommodation for its valuable library.

When the building now occupied by the society was vacated two years ago by the Edinburgh Life Assurance Company, operations were at once begun by the Board of Works to fit it for its new function. No structural changes of magnitude were needed to make the rooms effective for their purpose. The late librarian, Mr. Hardy, whose lamented death last spring deprived the society of a singularly efficient and devoted officer, had meanwhile been planning the whole arrangements of the library, and what is now seen is largely the result of his forethought and attention to details.

The building is entered by two doors. The east door is open daily, and through it entrance is at once gained to the front saloon, where there is every convenience for reading and writing. The west door is opened only on meeting days. It leads directly into a staircase, by which immediate ingress is gained to the meeting-room, which is fitted with a lecture table and appliances of various kinds. By the same staircase, also, access is had to the reception room on the first floor and to various library rooms on the second floor.

The guests on the night of the reception passed up the west staircase, at the first turn of which a fine bust of Cuvier greeted them with calm dignity.

Along the walls of the meeting-room (transformed for the occasion into the cloak-room) some other interesting busts are to be seen—Berzelius, John Playfair, Rev. Sir H. Moncrieff Wellwood, and Sir Walter Scott; also an engraving of the statue of Sir Joseph Banks in the British Museum, executed by Chantrey. A photograph of Sir Richard Griffith and an engraving of D. Milne Horne also decorate the walls.

Passing out of the meeting-room and up a few steps we come to the ante-room, with oil portraits of James Watt and William Murdock, one of the pioneers of gas lighting. In the handsome reception-room immediately adjoining are portraits of former well-known presidents and secretaries—Sir T. Makdougall Brisbane, Sir James Hall, Profs. J. D. Forbes and John Robison, the last a Raeburn; also a bust of Sir Roderick Murchison occupies one corner. Passing across the reception-room we emerge at the head of the east staircase, which leads down to the front saloon and to the east door. The portraits which decorate the walls of this fine staircase are (beginning from the top) those of Piazzi Smyth, Patrick Neill, Sir David Brewster, Sir Robert Christison, Sir Walter Scott, and the first president, Henry, Duke of Buccleuch. In addition to these there are several good engravings of portraits of Henry Mackenzie (the "Man of Feeling"), the Right Hon. Jas. Moncrieff, and Dr. William Robertson, the historian (a fine engraving by J. Dixon from the portrait by Sir Joshua Reynolds).

The front saloon has its walls covered with books, and contains a life-like bust of James Gordon, the late librarian. Opening off it at the north-west corner is the librarian's room or office, with a portrait of Sir Humphry Davy over the mantelpiece. Adjoining it is the council-room, with the well-known portrait of Prof. Tait (by Sir George Reid) hanging above the fireplace, and on each side a drawing of the birthplace of Sir Isaac Newton, presented to the society by a son of Prof. Robison. The same donor also gave a small carved door, which formed part of a book-press belonging to Newton. Passing out of the council-room by a door in front of the foot of the east staircase, and turning along a passage to the right, we come to a large oblong room called the back saloon. Round the walls are steel book-cases filled with the Transactions and Proceedings of various scientific societies of foreign countries. The countries are arranged alphabetically, and under each country the towns are similarly arranged, so that a visitor has not the least difficulty in finding the shelves on which the publications of any given society are placed.

Near the council-room door a staircase leads down to the basement, where, in addition to rooms set apart for shelving books, are strong-rooms for storing the society's own Transactions and Proceedings, and the blocks and plates of illustrations. These are all admirably arranged, so that the stock in hand can be estimated almost at a glance.

Taking a general survey of the contents of the many book-cases which line the walls of the various rooms, we soon recognise the guiding principle of the whole. The front saloon or reading-room contains such journals and periodicals of a general scientific character as are most in demand. The librarian's room contains mathematical journals, the society's own publications, and the various scientific catalogues and dictionaries. In the council-room the reports of scientific expeditions find a place, and the quarto volumes of the American and Indian Geological Surveys, and much of a connected nature. The back saloon has already been described. In the basement we find journals of zoology, botany and medicine, electrical engineering, meteorology, geodesy, geology, &c.

There are no book-cases in the meeting-room or reception-room, but on the second floor there are three fairly large rooms and one small room filled with books. In one we find periodicals and books bearing on geography, biography, philosophy, philology, in another astronomy, and in a third the literary weeklies, monthlies, and quarterlies.

This description is not, of course, exhaustive, for, besides the periodical publications, the Royal Society of Edinburgh possesses many books of historic value and antiquarian interest; also the complete works of famous men of science from Galileo down the centuries. It will serve, however, to show that, as regards the accessibility to their literary treasures, the society has distinctly benefitted by their change of location.

The reception-room on the first floor, where the fellows meet for tea and talk before the afternoon meetings and after the evening meetings, has been beautifully designed, largely under the advice of Sir George Reid.

The least satisfactory of all the arrangements is the meeting-room for the reading of papers, but it is difficult to see how anything better could have been done. The lecture table, with gas fittings, occupies part of one of the long sides. The lantern-screen partly covers the black boards on the wall behind, the lantern being ensconced in a niche in the opposite wall. The hangings and decorative busts have practically killed the echo which was heard when the room was first tried. Yet to the many fellows who remember what used to be, the present arrangement lacks a certain undefinable flavour of old-world dignity. There is too much of the modern lecture-room and too little of the feeling of a scientific and literary society met for the interchange of views.

In other respects, however, the society has gained much by its removal from the limited space at its disposal in the Royal Institution to the spacious accommodation in George Street. Its remarkable collection of portraits and busts can now be seen to advantage, and the ready accessibility to its valuable library of books and periodical literature in all departments of science and in many departments of philosophy and art cannot but confer a great boon to the fellows and others engaged in research work.

The reception on Monday night was a large gathering, representing all phases of national life, such as Parliament, the Church, the Bench and the Bar, other legal bodies, the Scottish universities and leading educational institutions, the Royal Academy, municipalities, parish councils, &c.

THE INTERNATIONAL INVESTIGATIONS IN THE NORTH SEA AND THE SCOTTISH BOARD'S ANNUAL REPORT.[1]

SIX years have now elapsed since the commencement of the international fisheries' work by the seven nations concerned, and with the bulky literature and masses of tables and plates in hand it may be thought that now a stage has been reached which will demonstrate one way or another the position of the sea-fisheries, especially as it was stated that results of importance were early to be forthcoming. Yet in scanning the various publications no very definite general conclusions are apparent, and the question of primary importance to this country remains—excepting the statistics of the bureau—as far from solution as ever. To take the publications in the order abovementioned, the first is Dr. Kyle's important statistics of the North Sea fisheries for 1906. So far as can be observed, the total of the sea-fisheries of each nation shows an increase both in quantity and value on the previous year (1905), with the exception of Ireland. In the case of such fishes as the cod and the haddock, the ever-recurring variability displays itself in an increase of both in Denmark and the Netherlands, a diminution in Germany, an increase of cod and a diminution of haddock in Belgium, an increase of cod in Sweden, and a great increase of the same fish in England and in Scotland. Along with this is a considerable diminution of plaice in Sweden, England, and Belgium, and a considerable increase in Scotland and the Netherlands, a great increase in Denmark, and a nearly stationary condition in Germany. Dr. Kyle points out, however, that this decrease is due to a diminished capture of the smaller sizes of plaice (*e.g.* in England, Holland, Germany, and Belgium). Much has been written about the decrease of the lemon-dab (or so-called "lemon sole") in Scottish waters, yet in 1908 it brought 70,134*l.*, or 1400*l.* more than in the previous year. In the same way, whilst the sole and the turbot vary in the different nations, the dab remains stationary in Scotland, where it was supposed by its increase to be ousting the plaice. These statistics, which cover a much wider area than it is possible to allude to here, are perhaps the most important result of the international scheme, and they show how uncertain and variable sea-fishing is. Moreover, they demonstrate that whilst in one country the capture of a species may temporarily be diminished, in another it is increased. The comparative constancy of the totals and the large amount of fluctuation in individual species are points emphasised by Dr. Kyle. Further, no Continental nation approaches the share taken by Britain in this industry, England having 39 per cent. and Scotland 34 per cent. as their respective shares, the nearest being Holland with 12 per cent., Germany having only 4·7 per cent.

The report of the International Council between July, 1907, and July, 1908, is chiefly occupied with the record of changes in the *personnel* and an epitome of the seventh annual meeting at Copenhagen. It is noteworthy that the council is still in want of information concerning important fishes, such as the plaice, flounder, and other flat fishes, the haddock and other gadoids, and the herring and mackerel of the North Sea. Anything like finality in its labours seems as far distant as ever, yet hydrographical and "plankton" work still hold it. Prof. Garstang, moreover, gives an interesting account of the distribution of the plaice in the North Sea, Skagerak, and Kattegat according to size, age, and frequency, no fewer than 2048 hauls of the trawl and 327,000 examples of plaice having been dealt with; yet the decline in the returns from Sweden and Belgium after 1904, and from Scotland after 1905, must seriously affect the scope of the results. In regard to general distribution, the facts corroborate those elicited in 1884,[1] viz., the occurrence of small plaice in shallow water and of large in the deeper water, with a constant interchange between the two areas. Yet it is impossible to establish a hard-and-fast correlation between the size of the plaice and depth. The very general distribution of this species over the North Sea is a further guarantee for its safety. Mention is made of "dense" accumulations of plaice in the "protected Scottish Firths," but such accumulations were there before protection existed. It is stated that from fifteen to twenty plaice of 35 cm. were caught per hour in the inner part of St. Andrews Bay, information which will cheer the fishermen there, since for thirty years at least the uniform sizes caught for sale have been from 10 inches to 13 inches. The idea that many large plaice leave the Firth of Forth and enter St. Andrews Bay during the autumn, thereafter proceeding to deeper water to spawn, and again swell the ranks in the Forth, is in need of confirmation. Similar remarks apply to the changes noted in the large plaice of the Moray Firth. Minimum captures on the inner areas or outer "deeps" are not necessarily connected with "migrations." The remarkable oscillations described as occurring in the small plaice of the eastern area of the North Sea, viz. that they pass outward and again "work their way backward" inshore, would have been less phenomenal and would not have required the aid of "hibernation" if researches on the same size on the western shores (British) had been systematically carried out, along with an inquiry into the early post-pelagic and subsequent stages below the sizes selected. Migrations, indeed, loom largely in the international work, even to the supposition that the cat-fish (Anarrhichas) is as regularly migratory in the spring as the hake is in autumn. Moreover, large plaice were common in the Moray Firth before its closure, and are still there, the smaller finding ample scope in the shallows and the larger sufficient depth within the area. In regard to seasonal changes in the stock of plaice, it has long been known that captures in mild weather are greater, and that a cold, frosty morning diminishes them, but it does not follow that such captures give trustworthy information as to "maximum and minimum densities." The changes on the various "banks" naturally follow the spreading of the younger plaice seawards, but "hibernation" of small plaice and immigration of large, mature fishes rest largely on conjecture, as does also the notion, marking notwithstanding, that large numbers of mature fishes "migrate from the north for spawning purposes." The supposed scarcity of large plaice in the deeper water in winter may be due to other causes than migration, though congregation for spawning purposes is reasonable. Mr. Hefford's paper on the proportionate distribution of the sexes of plaice in the North Sea does credit to his ability, but his conclusions would need the support of longer experience, especially as a large inner area, viz. from Montrose to Kinnaird Head, has been omitted. The notion that the proportion of sexes of plaice may yet indicate the intensity of trawling in a given region is scarcely warranted.

Twenty-seventh Annual Report of the Fishery Board for Scotland for the Year 1908. Part i., General Report. (Edinburgh: Oliver and Boyd.)

[1] Scientific Trawling Report, pp. 21, 25, 43, 76, &c., 1884, and in General Report, 1885, correspondingly.

Vol. x. consists of a bulky report dealing with the whole period (1902–7). It reiterates the problems to be solved and the methods followed by the administrative committee, with a summary of the results, besides a series of special reports by seven responsible authors. Some of these reports have previously been published, and have received attention elsewhere, so that they need not be alluded to. In the summary of the results the administrative body deals first with the depths and hydrography of the oceanic regions investigated. Then the spawning conditions and spawning places of the gadoids (seventeen in number) are considered, and it is to be noted that the investigation of both is now held to be complete, a view some may doubt, considering the scattered cruises of the steamers, and when on the next page it is stated that the spawning places cannot always be given with absolute certainty. The summary is full of interest, but in the case of several species the limitations given by the committee need re-investigation, and, for instance, no differentiation of the areas of the British coast has been attempted as regards the cod. The third head treats of the "natural conditions in the spawning regions," and an effort is made to connect temperature and salinity with the spawning process. The gadoids, however, are not the only fishes in these waters, and there is perhaps little more in the matter than that an Arctic, a temperate, and a tropical fish finds—each in its own waters—the most suitable spawning conditions. Besides, the refinements of temperatures and salinities, however interesting scientifically, count for little in the main question put before the investigators by the British Government. It was well known that wherever the conditions of life were suitable, there the pelagic larvæ and young fishes were found with great regularity, irrespective of currents, temperatures, and salinities. No current is known which will take the larval cod with unfailing regularity in one direction and the haddock in another, which will keep the larval dabs and top-knots often in deeper water whilst the plaice is with unfailing accuracy sent to the margin of the beach. No currents, temperatures, or salinities will explain why in 1908 the herring fishing was very successful in the northern Scotch area and less successful in the southern, and why in 1909 exactly the reverse was the case. In this connection, Schmidt also gives no reason why the ova and fry of *Gadus luscus* are not carried far from their spawning place. What can those familiar with the subject make of the following:—"According to the spawning time, first the cod eggs, then the haddock eggs, and lastly the whiting eggs are involved in the movement of the currents"? It has not been shown that the currents which distribute the eggs of the pollack and the poor cod in the Atlantic in spring have their equivalents in the summer when the same fishes spawn in the North Sea, though there is little fear as to the safety and distribution of the eggs of these and all other marine fishes. The guarded remarks of the committee are therefore warranted, viz. "the investigations we are discussing here are far from being able to solve so great a problem." Especially does this apply to the notion that all the young green cod which swarm on the Scottish coasts have been spawned on the North Sea bank, and that the cod makes long migrations for the purpose of spawning.

On the important problem of sea-fish hatching the committee make very cautious remarks, basing their views mainly on Knut Dahl's paper. In this it is shown that in small Norwegian fjords where cod spawn the captures by tow-nets were not influenced to any extent by the addition of thirty millions, and that the captures varied much in different years. No difference also was noticed in the quantitative occurrence of young littoral fishes each year. They found no proof of an increase of local stock by artificial hatching, but they do not discourage further experiments. The foregoing is in marked contrast with the results of Fulton in the upper waters of Loch Fyne, where shore-fishing with a push-net found an increase of young plaice during the six years in which 141 millions of young plaice were added, as compared with the following six, in which none were added. Yet in glancing at his figures it would appear that in four of the years in which none were added the average captures per hour compare favourably with those in which millions were put in, and, further, that a fifth year is second highest on the list even of the favoured years. The chances of error in work carried out in the circumstances, and the great variation from eight to 112 per hour when no addition was made, combine with other points to render this experiment in need of confirmation.

Seventy pages are devoted by the administrative body to the distribution, growth, and migrations of the older stages of the important food-fishes, and to some practical fisheries questions in the light of the results obtained. Under the former head the cod, haddock, and whiting alone are dealt with, the ages being determined by measurements by Helland Hansen, who finds little variation in the numbers of large and extra large haddocks during the years of investigation, and by the rings on the scales by Damas, whose prolix paper might well have been abbreviated. The reliance on the catches, for instance, of the haddock, in the deeper water of the North Sea as proving migration is open to question, and the remark by the administrative body that the reporters are not warranted in explaining the "marked" seasonal migrations, some of which are connected with the occurrence of shoals of herring, is safe.

One of the most interesting and important contributions is that of Johs. Schmidt, on the distribution of the pelagic fry of the gadoids and the spawning regions of the gadoids in the North Atlantic from Iceland to Spain. He lays, however, too much stress on his experiences of Icelandic currents in treating the conditions in the North Sea, and shows too evident a tendency to make out a case for the hydrographer.

Of the Scottish Board's report, it need only be said that it proves the prosperous condition of the Scottish fisheries, for though the total does not reach that of the previous year (1907), yet the deficit is due solely to herrings, the "catch" of other fishes being greater in 1908 than in 1907. It is a decade since the ruin of the lemon-dab ("lemon sole" of the Board) was in sight, yet the "catch" of this fish exceeded by almost 1200 cwt. that of 1907, when the record did not vary much from the preceding years. It is sometimes forgotten that the amount of flat fishes rises or falls according to the amount of energy expended in their capture, not because any noteworthy change has occurred in their numbers.

To sum up the international work, then, it would seem that considerable waste of energy and funds is caused by the re-publication of papers, and by the manner in which several of these overlap. Moreover, it is beyond the scope of science to enter into a disquisition on the fluctuations of the market-price of fishes. It is also noteworthy to find that, after seven years' work, the council now see the magnitude of their task and the absence of finality in their labours. There is no sign of "impoverishment"; on the contrary, their cautious words lean to the opposite view. The committee recommend continuation of their labours, basing this on the fact that various nations share in the North Sea fishing, and that no action could be taken without the consent of the other countries; but as to any important result to be gained by the fisheries there is silence, for it cannot be supposed that hydrography, the collection of fish-food and bottom deposits, can do duty any longer as necessary measures for the welfare of the North Sea fisheries.

W. C. M.

THE ASSOCIATION OF TEACHERS IN TECHNICAL INSTITUTIONS.

AT the fifth annual meeting of the Association of Teachers in Technical Institutions, held on Saturday, November 6, Mr. J. Wilson, of the Battersea Polytechnic, president of the association, in moving the adoption of the annual report, reviewed the year's work. In the course of it he laid special stress upon the very important step taken by the association, at its conference at Liverpool, in putting forward a definite series of resolutions relating to educational reforms which appear to them as teachers to be essential to the continued progress of technical education. In these resolutions the association expresses its opinion that it is necessary to raise the school-leaving age to fifteen years; it asks that special attention be given to the teaching, in primary schools, of elementary science, practical arithmetic, and manual training; it calls for complete coordination of the work of the evening continuation schools with that of the evening technical schools; it asks for the provision of technical-secondary schools, including trade schools, with a generous system of scholarships, including allowance for maintenance; and, finally, it endorses the recommendations of the Minority Report of the Poor Law Commissioners respecting compulsory attendance of boys for technical instruction for not less than thirty hours per week. Thus a very definite policy in some important educational problems affecting technical education has been taken up by this association.

Another important, and in this case non-controversial, action is now being broached by this body of teachers. It suggests the desirability of holding a series of "round table" conferences between accredited representatives of primary, secondary, and technical teachers, with the object of discussing the possibility of reforms in the curricula and methods of work in the schools, from the point of view of the needs of the pupils who at a later stage pass on to the technical schools. Most urgent is the necessity for such conferences in the case of the primary and technical teachers, in order that they may arrive at a mutual understanding of the needs of the pupils and the possibility of meeting them, because in the majority of cases where pupils receive any formal teaching after the primary-school work, it is to the technical teachers that they come for it. Such conferences abound with immense possibilities for the benefit of education in all its phases. Broader and more complete knowledge of each other's branch of work and its needs and possibilities must necessarily result, and as a consequence many apparent difficulties in the way of making the educational work in the two or three types of school truly continuous, without unnecessary overlapping, will be removed. The better knowledge of each other's work will remove some prejudices and bring about the necessary unanimity of action in those matters which affect the teachers individually and as a class, such as conditions of service, security of tenure, and superannuation for all classes of teachers; these views being held by the association, it is all but unnecessary to point out to any other class of teachers, who have the duty, responsibility, and honour of teaching the pupils in their earlier years, that criticisms made by this association on the preparation of those pupils for later technical studies is not directed at the teachers, but at the systems imposed upon them, in which ideas, good in themselves, are allowed such sway as to mask the greater essentials of elementary-school work.

In 1888 Parliament passed a Technical Education Act, and for the past twenty-one years progress has been vigorous and rapid. Nevertheless, technical education has touched only a very small fraction of the enormous mass of material represented by the workers of all grades in the industries of the country. We can only regard it as having entered upon its duties, and must look forward to dealing with much larger numbers of students and to a greater range of work. There are two chief factors which may assist in bringing in much larger numbers of the young workers. The first of these is the increasing interest and help of the employers. Efforts in this field have so far produced but scanty results, and the association as a body is not very hopeful of this field. The second factor, to which the association looks with greater hope, is some form of organised effort by the State to achieve the following ends:—

(*a*) Elementary education to be made more real and practical; less "bookish," without diminishing its cultural value.

(*b*) The establishment of some system of compulsory attendance for continued education for all between the ages of fourteen and seventeen years.

(*c*) The linking together of the three main grades of educational effort.

(*d*) The complete coordination of the work of the evening continuation schools with that of the evening technical schools.

It is agreed by many observers, within and without our technical institutions, that technical education is rapidly approaching a crisis in so far as its higher work is concerned in the London polytechnics. The special feature of the moment is the relation of technical institutions to the university colleges. The association holds the opinion that there is room and to spare for the activities of both in those phases of their work which are common, and fully recognises that each has its own special function. It claims that the opportunity for complete study should be within the reach of every capable student, and that, too, in a sympathetic atmosphere. There is visible at the present time, both in London and the provinces, a tendency, under the guise of coordination, to curtail this higher work in both science and technology in these technical institutions, and thus to reduce seriously the students' opportunity. This tendency, if carried into effect, would be disastrous, under present social conditions, to the highest interests of national education, especially as regards the evening students.

H. ADE CLARK.

AN ORNITHOLOGIST IN QUEENSLAND.

IN June last the editors of the *Emu* issued a special number (vol. viii., part v.) containing a very interesting account, by Mr. S. W. Jackson, of a trip to northern Queensland in search of the nest and eggs of the tooth-billed bower-bird (*Scenopaestes dentirostris*). The expedition was undertaken on behalf of Mr. H. L. White, and appears, in spite of many difficulties, to have been eminently successful in the attainment of its object. The exploration of the tropical forests of Australia is by no means devoid of danger. Mr. Jackson himself was laid up for a week with "Johnstone River fever," which he regards as the almost inevitable price of his wanderings in the moist, fever-stricken scrubs, and one of his natives was killed by the falling branch of a tree, while the "scrub-itch mites" appear to constitute a plague of no mean order. It was a long time before he succeeded in obtaining the nests and eggs of the tooth-bill, though the playing-grounds were met with in great abundance.

A detailed, though unfortunately somewhat disconnected, account is given of the habits of these truly remarkable birds. They were first observed shortly before the commencement of the breeding season, each one occupying his own particular playing-ground without a mate. The play-grounds are cleared from dead leaves and other débris, and decorated with large fresh leaves placed face downwards. The leaves used are of various kinds, though sometimes only one kind may be found in a particular play-ground. The work of decoration is carried out afresh every morning, the leaves of the previous day being thrown on one side and new ones substituted. "Up to 6 a.m. they appeared to be hard at work clearing their bower floors of the old leaves and re-carpeting them with fresh ones, and until this early house-work was done they appeared to be in little mood for song or mimicry. I came across them hard at their re-furnishing, and carrying the long, heavy leaves in their bills *by the stems*, and just as they had severed them from the trees." The birds feed upon a kind of red berry, not yet identified, and the author is inclined to think that the serration of the beak has nothing to do with the collection of food. It is, however, apparently of use in cutting or sawing off the leaves for the decoration of the playing-ground, as was actually observed.

The tooth-bills are wonderful mimics, and Mr. Jackson gives a graphic account of their vocal performances. They seem able to imitate almost all the characteristic sounds of the forest, from the distinctive notes of other birds to the "pulsating rattle of a captured cicada."

After many disappointments the nests were at length found in very tall trees, very loosely constructed of twigs and containing only two eggs of a uniform brown colour. The character of these eggs leads the author to the conclusion that the tooth-bill is really a cat-bird, and not a true bower-bird at all. We cannot refrain from quoting the description of the finding of a pair of these eggs:—"The nest is placed fully 90 feet from the ground, in a mass of dense vegetation at the top of a bean or scrub chestnut-tree (*Castanospermum australe*). The climb is an awkward one, and our best black, who had examined the nest in the first instance, is again chosen to tackle the task. Strapping the egg-pouch around his waist, I say 'Good luck!' and up he goes. Placing the perpendicular and suspended vines between the first and second toes of each foot, he simply walks up, with marvellous and untiring agility. Making his way through the masses of vines and foliage near the top, he at length gains the rare nest, and suddenly exclaims, 'Two pfeller heg sit down!'"

Although the tooth-bill was the main object of the author's quest, the account of his wanderings contains much interesting information about other birds and some very good photographs, and is well worthy of perusal by all field naturalists.

INTERCHANGE OF UNIVERSITY STUDENTS.

In July last (vol. lxxxi., p. 55) we directed attention to a scheme, which is in course of development, to provide an interchange of university students between the United Kingdom, Canada, and the United States. It was pointed out on that occasion that the objects in view are to enable as many as possible of the educated youth of the countries named to obtain some real insight into the life and customs of other nations at a time when their own opinions are forming, with a minimum of inconvenience to their academic work and the least possible expense. The scheme will afford technical students facilities to examine into questions of interest to them in manufactures and so on, by observation in other countries, and will allow men of one part of the Empire to realise the needs and potentialities of the others.

Among the immediate needs of the executive committee in charge of the scheme, it may be mentioned that, to cover the estimated expenses of twenty-eight annual travelling scholarships, and of two students' travelling and information bureaux (one in Great Britain and one in America) for a provisional period of three years, in which the value of the scheme can be successfully demonstrated, a total sum of 13,000*l.* is needed. This is to be raised in three amounts, proportionate to the expenses incurred:—from the United States, 4500*l.*; from Canada, 1800*l.*; and from the United Kingdom, 7500*l.* There is not likely to be any difficulty in raising the money required in Canada and the United States. British students will incur more expense than others on account of the distances to be covered on the other side by the scholars, who will travel through Canada to the Pacific coast and return *via* the United States.

The committee hopes to be able to complete the organisation so that exchanges may be effected for 1910. To enable this to be accomplished, the treasurer (Lord Brassey) should receive promises to the amount of 7500*l.* within the next month.

Thanks largely to the practical support of the president of the movement (Lord Strathcona), who combines the Chancellorships of Aberdeen and McGill Universities with his work as High Commissioner of Canada, a central office has been established at Caxton House, Westminster. The travelling students will have the advantage of reduced rates of travel, of the special information which the bureau will be able to afford, and of the privilege of being brought, so far as possible, into contact with the actualities of those countries to which they go, whether persons, places, or institutions. A publication of great utility in connection with the movement will be compiled by the bureau.

The arrangements for the other side of the Atlantic also have made good progress. There is to be a bureau in New York under the direction of an American secretary, while at either Montreal or Toronto there will be a representative of the Central Bureau established in London, which forms the headquarters of the movement and the centre for the British Empire. In this connection, also, it may be mentioned that hopes are entertained of the opening in London of a common room for the convenience of the students concerned. The movement has been taken up by prominent educationists and others in the United States and Canada. Under the direction and guidance of the bureau the scholars, selected in the manner previously described, will travel for ten weeks during the long vacation through the respective countries. In order to elicit close observation, a detailed report of the tour will be required from every scholar. Donation forms, and all further information, can be obtained from the honorary secretary, the International Interchange of Students, Caxton House, Westminster, S.W.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

We learn from the *Revue scientifique* that the inauguration of the new Swiss university at Neuchatel took place on October 19. The University has grown out of the Neuchatel Academy, which was founded in 1866 and was re-organised in 1894.

Major Craigie, the Gilbey lecturer at Cambridge in the history and economics of agriculture, will give two lectures on "The History of Canadian and Australian Development and its Effect on British Agricultural Conditions" on November 17 and 18, at 5 p.m., in the University Chemical Laboratory.

Prof. Percival has resigned the directorship of the department of agriculture and horticulture of University College, Reading, and has been appointed to the post of professor of agricultural botany. Mr. Ronald V. O. Hart-Synnot has been appointed director of the department of agriculture and horticulture in succession to Prof. Percival.

The trustees of Princeton University, we learn from *Science*, have accepted the gift of 100,000*l.* of Mr. W. C. Proctor, of Cincinnati, made on condition that an equal sum be obtained by May 1, 1910. Haverford College has received 20,000*l.* to establish a fund for pensioning its professors. The General Education Board in the United States has made a conditional grant of 25,000*l.* to Ohio Wesleyan University, at Delaware, O. Mrs. Charles E. Perkins, of Burlington, Ia., has given 6000*l.* to Harvard University, to establish scholarships for students from Iowa. Harvard University also has received gifts amounting to 1320*l.*, to be used for the immediate benefit of freshmen in Harvard College.

The President of the Board of Education received a deputation from the County Councils Association Rural Education Conference on November 3. At a meeting last July the conference passed resolutions in favour of manual training, such as handicraft and gardening for boys and needlework and cookery for girls. On behalf of the deputation, Mr. Hobhouse explained that the resolutions were intended to express a widespread and growing feeling that elementary education should be brought into closer touch with the practical activities of daily life. The agricultural classes have hitherto been unduly prejudiced against the present system of elementary education as being mere book-learning, tending to unfit children for industrial occupations and calculated to produce only clerks and errand boys. The resolutions state that in the opinion of the conference it is not only desirable, but essential, that some form of manual training shall be given in every elementary school and throughout school life. It is often impossible, in the first place, to find teachers qualified to give the necessary instruction. The second difficulty is that of buildings and equipment. Wherever possible in rural schools a room should be provided and a plot of ground secured for practical instruction. Thirdly, while in concentrated populations the present grants for special subjects may be adequate, they are quite insufficient as regards scattered populations. In his reply, Mr. Runciman said the object of the Rural Education Conference may be summed up shortly—that it is sought to make the education of the children in the public elementary schools more practical and less bookish, to make it, in fact, deal more with things than with ideas, and to adapt it more to the special requirements of particular localities. With these objects he said he is in general sympathy, and the Board of Education has shown its approval of them by the changes it has made in the curriculum. The Board has attempted, so far as possible, to encourage the experiments enumerated by the conference; the real pity is that the experiments are so few. This is the fault of the teachers and the local authorities. Even in cases where the equipment is so small that it is impossible to carry on the work, the Board has done what it can to encourage the work of the peripatetic teachers. The gardening classes in elementary schools, as shown in the statistics of his department, have largely increased in number of recent years, and only within the last few weeks an important new departure has been made in arranging for the coordination of the work of the Board of Education with that now done by the Board of Agriculture.

LORD ROSEBERY, as Chancellor of Glasgow University, presided on November 5 at a dinner of the Glasgow University Club, London. In proposing "The University and the Club," Lord Rosebery remarked that there is nothing more interesting at this moment in the non-political aspect of England than the sprouting up of new universities all over the country. This shows an uprising of an intellectual interest which is full of promise at a time when all in the future of this country does not seem equally happy in expectance. These universities are the result of a real desire on the part of the people to partake of the higher, and perhaps even more of the technical, education that the universities afford. The universities are an outward and visible sign of a grace which is not likely to remain inward, but is likely to show itself in the influence of our national destinies. Lord Rosebery later remarked that he cannot help watching with an intense and almost a timid interest the outcome of the teaching of the universities. The destinies of this country are likely to be moulded indefinitely for good or for evil, in the course of the next few years, by the men of ability, and still more the men of character, who rise in each generation to mould their fellows. He hopes that the University of Glasgow will have many such missionaries of Empire, many men who are prepared with strong backs to wrestle and to stand for the truth, to oppose error in whatever place they may find it, and to remember that though they may be working in their own professions, for their own aims most of their time, yet there is part of their time which they owe to the traditions of their own university and to the welfare and future of the Empire itself. Lord Rosebery believes that Oxford and Cambridge have a great task still before them in the advancement of studies which must always appeal to a large, a leisured, and a learned section of the nation; but he is doubtful if grafting on to the ancient institutions newer technical schools is likely to answer to them or to the schools which they are attempting to found. Every university has, or should have, a character of its own, and the characters of Oxford and Cambridge are so strongly marked out, and they have so venerable a tradition to support them, that they need no special modern adjuncts, and Lord Rosebery doubts that they are likely to profit by them much, for, in truth, on the new grounds they cannot compete with the newer universities. The newer universities were founded with the object of promoting those practical and technical branches of knowledge for which the increasing demands of the age have gradually called.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 4.—Sir Archibald Geikie, K.C.B., president, in the chair.—Colonel Sir David **Bruce**, Captains A. E. **Hamerton** and H. R. **Bateman**, and Captain F. P. **Mackie**: (1) The development of *Trypanosoma gambiense* in *Glossina palpalis*; (2) a note on the occurrence of a trypanosome in the African elephant.—The Lord **Rayleigh**: The perception of the direction of sound.—Prof. H. M. **Macdonald**: The diffraction of electric waves.—R. **Houstoun**: The mechanism of the absorption spectra of solutions.—Hon. R. J. **Strutt**: (1) Note on the spontaneous luminosity of a uranium mineral; (2) the accumulation of helium in geological time, ii. The second paper is a continuation of that published in Proc. Roy. Soc., A, vol. lxxxi., 1908, p. 272, the object being to determine the ratio of helium to radio-active matter in minerals as a means of measuring their age. The data given refer chiefly to the iron ores of sedimentary strata. Even some of the most recent are found to contain quantities of helium, denoting great antiquity. Thus ironstone from the Eocene beds of Co. Antrim contains, per gram, $2{\cdot}64\times10^{-4}$ grs. uranium oxide (U_3O_8), $8{\cdot}27\times10^{-4}$ grs. thorium oxide, and $12{\cdot}1\times10^{-4}$ c.c. helium. This, interpreted according to the best available data, would imply an age of thirty million years. Experiments of a preliminary character have been made to determine directly the rate of growth of helium in thorianite and in pitchblende. The data thus obtained will give the rate of formation of helium by the complete series of uranium and thorium respectively, and thus make it possible to interpret more definitely the results of experiments on other minerals for which a direct determination is not feasible; 400 grams of thorianite was found to yield in seven weeks a quantity of helium certainly less than 2×10^{-6} c.c. The annual rate of production per gram of thorianite is, therefore, certainly less than $3{\cdot}7\times10^{-8}$ c.c. The 9 c.c. initially present cannot, therefore, have accumulated in a less time than 240 million years. An experiment on pitchblende of a similar character was consistent with Rutherford's estimate of the rate of production by the uranium series, but was not on a sufficient scale to afford complete confirmation. Experiments on a larger scale are in progress.—J. C. **Chapman** and H. L. **Porter**: The physical properties of gold leaf at high temperatures.—Dr. H. C. **Pocklington**: The dimensions and function of the Martian canals. The nature of the bed of the canals is guessed from Lowell's value of the velocity of flow along them, and then the depth is calculated from the technical formulæ, assuming that the canals are horizontal and carry water from pole to pole. The depth is 500 feet if the canals are as narrow as possible, or 370 feet if they are 4500 feet wide. The amount of water required to fill the canals is determined. To find the function of the canals, it is assumed that their arrangement is the most economical, and it is deduced that they are essentially lines of communication, though, of course, they may also serve to carry water for irrigation.

Physical Society, October 22.—Dr. C. Chree, F.R.S., president, in the chair.—F. E. **Smith**: Cadmium amalgams and the Weston normal cell. Cadmium amalgams may be solid, liquid, or a mixture of solid and liquid phases, the composition of the phases depending on the temperature. When a liquid amalgam is cooled below the lower transition temperature, the centre of the resulting solid is of high cadmium concentration, and the outer skin of low cadmium concentration. Diffusion tends to produce uniformity, and in consequence the E.M.F. of a cell containing the amalgam is unstable for a considerable length of time. When the amalgam is cooled to a temperature a little below the lower transition temperature, the difference of concentration between the inner and outer parts of the amalgam need be only small to enable the outer skin to be a two-phase system. The diffusion process will be slow, and the E.M.F. may remain constant for a long time. Amalgams which were of uniform cadmium concentration were obtained by chilling liquid amalgams to a temperature of about −50° C.; although not initially stable, rapid diffusion processes resulted in these amalgams becoming approximately uniform throughout after a few days, and their electromotive properties were different from those of slowly cooled amalgams. The experiments indicate that a 12·5 per cent. amalgam may be used safely at all temperatures between 12° C. and 60° C., and a 10 per cent. amalgam at all temperatures between 0° C. and 51° C. Experiments were made on the temperature coefficients of the anode and kathode limbs of the Weston normal cell, and show that if a difference of temperature of 1° C. exists an error of about 3 parts in 10,000 is introduced.—F. **Soddy**: Production of radium from uranium. The measurements on the growth of radium in the three uranium solutions purified between three and four years ago have shown that in all the growth of radium is proceeding at a rate proportional to the square of the time. The ordinary error is not greater than 10^{-12} gram of radium. This result indicates the existence of only one long-lived intermediate product in the series between uranium and radium. The period of average life of this body is 18,500 years in the case of the oldest solution for which data are available; but for the solution prepared last, the period indicated is about half again as long as in the first experiment. Had this solution grown radium at the same rate, with reference to the square of the time, as the older solution has done during the past year, more radium should have been formed than the *total* amount now actually present. This suggests the existence of at least one new intermediate product in the series "uranium A." From a mathematical investigation of the effect of such a body on the rate of growth of radium, it is concluded that it would not, if it existed, appreciably alter the production of radium over the period accurate observations have been made; but its existence would vitiate the calculation of the period of the direct parent of radium according to the simple formula neglecting short-lived products.—F. **Soddy**: The rays and product of uranium X. Experiments have been made with the uranium X preparations separated from 50 kilograms of pure uranyl nitrate. There occurred the growth of a feeble α radiation as the intense β radiation decayed. Such a growth of α rays, concomitant with the decay of β rays, is to be expected if the parent of radium is the direct product of uranium X. From the period of the parent of radium, the uranium X in equilibrium with 1 kilogram of uranium should give by its complete disintegration a product having the α activity of 2 milligrams of uranium if no new intermediate bodies intervened. The preparations of uranium X were examined in a magnetic field sufficient to deviate all rays having a value for $H\rho$ less than 8640, but the still undeviated β radiation produced a leak in the electroscope several times greater than that due to the γ rays. These difficultly deviable β rays are similar in general character and in the value of their absorption coefficient to ordinary β rays. The first measurements were made in an electroscope filled with air. Later, the electroscope was filled with hydrogen, which constituted an enormous advance, and these experiments have shown that the α radiation of the preparation remains constant as the β radiation decays. Anomalies have been encountered with the difficultly deviable β radiation, which appears to vary in intensity according to the conditions; but throughout the "difference leak" between the preparation bare and covered, due to α rays, has remained constant in all the preparations examined. These measurements of the α rays, for different preparations, cover a period from immediately after preparation to nearly a year in the case of the main preparation, and longer periods in the case of weaker preparations. The two most recent preparations each contained the uranium X in equilibrium with about 5 kilograms of uranium, and the growth of α rays if the change of uranium X into the parent of radium were direct should be equal to the α radiation of 10 milligrams of uranium. The parent of radium cannot be the direct product of uranium X. The experiments indicate that it is not a product of uranium X at all, but the subsequent history of the uranium X preparations must be awaited before this can be decided.—F. **Soddy**: The production of helium from uranium and thorium. Helium has been detected in four experiments with uranium, in three with thorium, and in one with pitchblende solutions carried out according to the methods already published. Recent experiments with nearly a year's accumulation of helium from about 2 kilograms of uranium and thorium respectively have ended in failure owing to accidents.

Challenger Society, October 28.—Sir John Murray, K.C.B., F.R.S., in the chair.—Prof. d'A. W. **Thompson**: A new method of estimating the number of fish which escape through the meshes of the trawl. The first step was to envelop the trawl-bag loosely in a net of finer mesh, so that the catch was divided into larger specimens inside the trawl and smaller specimens between the trawl and the outer envelope. When curves of these two classes were plotted on the basis of numerous experiments, they naturally overlapped, the overlap representing fish of a length intermediate between those which could not possibly get through the trawl-mesh and those which were certain to slip through it. From the overlapped area a ratio could be deduced and tested in both directions against the curves, which appeared to give a fair measure of the small fish lost by an ordinary trawl without a finer envelope.

PARIS.

Academy of Sciences, November 2.—M. Bouchard in the chair.—M. **Le Chatelier** and S. **Wologdine**: The phosphides of iron. Of the nine apparent phosphides examined, only four have a certain existence, viz. Fe_3P, Fe_2P, FeP, Fe_2P_3, but the composition of the last two is not so certainly established as that of the first two.—A. **Calmette** and C. **Guérin**: Some properties of tuberculous bacillus of bovine origin, cultivated on glycerinated beef bile. Experiments had shown that when guinea-pigs were inoculated with bacillus cultivated in this manner, a much greater virulence was developed, this, however, becoming steadily diminished by successive cultures. Further experiments on horses and heifers showed that with the former the virulence was not only increased, but remained so, while the latter showed the decreasing virulence evident in the guinea-pig.—M. **de Forcrand**: The bicarbonates of rubidium and cæsium. They form anhydrous crystals, stable on exposure at ordinary temperatures, neither absorbing water nor evolving carbon dioxide. The solubilities are much greater than that of potassium bicarbonate, whilst they are also more stable under heat.—J. **Bosler**: Magnetic perturbations and solar phenomena. Observations were made on the violent magnetic storm of September 25.—A. **Perot**: A means of protecting the silvering of mirrors. This consists in re-covering the mirror with an extremely thin layer of transparent celluloid. If the layer is only sufficiently thin, images remain intense, complete, and do not show diffusion.—P. **Helbronner**: The geodetic complementary triangulations of the high regions of the French Alps. The number of geodetic stations in this district has been raised to 126, of which fifteen are above 3000 metres and forty between 2000 and 3000 metres.—M. **Darmois**: The composition of the essences of terebenthine. The method indicated, based on the measurement of rotatory dispersion, suggests that the essences of terebenthine contain (1) pinene under its two forms; (2) a lævo-carbide in large quantity.—M. **Devaux-Charbonnel**: Note on an attempt to realise an artificial telephonic line.—H. **Baubigny**: Action of heat on the sulphite and double alkaline sulphites of silver. Formation of dithionate. The author believes that during decomposition at 100°, in presence of water, of silver sulphite, and the double alkaline sulphites, the production of di-thionic acid is the principal result.—C. **Gerber**: Localisation of proteolytic ferments in *Vasconcellea quercifolia*. There seems to exist a relation between the enzyme-forming character of certain plants and the coagulability of their latex.—E. **Kayser** and E. **Manceau**: The viscosity ferments of wines.

These are thick bacilli, of length usually less than 2 μ; all are sugar ferments, and anærobic.—B. **Collin**: The hypertrophied forms and degenerated growth among the Acinetians. Intensive culture and constant over-feeding are capable of producing on the organism of these infusoria profound modifications, both morphological and physiological.—Ph. **Dantzenberg**: The marine molluscs found in the scientific expeditions of M. A. Gruvel in West Africa, 1906–9.—W. **Wietrzykowski**: Contributions to the study of the development of Lucernarids.—G. **Eisenmenger**: The glacial excavation of Lake Garda (Italy). If the origin of the Lake of Garda is a tectonic depression dating from Mesozoic, or if, later, different movements took place with a dislocation of Mount Baldo, it is necessary to recognise that the actual configuration of Lake Garda is the work of a very powerful glacial excavation.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 11.

ROYAL SOCIETY, at 4.30.—The Vacuolation of the Blood-platelets—An Experimental Proof of their Cellular Nature: H. C. Ross.—Further Results of the Experimental Treatment of Trypanosomiasis—being a Progress Report to a Committee of the Royal Society: H. G. Plimmer and Captain W. B. CYTOLOGICAL ASPECTS OF CERTAIN BIOLOGICAL PROBLEMS.

Zeitpunkt der Bestimmung des Geschlechts, Apogamie, Parthenogenesis, und Reduktionsteilung. By E. Strasburger. Heft VII., Der Histologischen Beiträge. Pp. xvi+124. (Jena: Gustav Fischer, 1909.) Price 6.50 marks.

IN the seventh part of his "Histologische Beiträge," Prof. Strasburger records and discusses the results of investigations on a number of cytological problems chiefly related to the nature and distribution of sex. The reader will recognise the facile grasp of wide and complex series of facts, as well as the lucid presentation of the conclusions, which form so strongly marked a feature of the works of this great investigator.

The opening chapter is devoted to an account of studies on the sexual differentiation in the spores of the diœcious liverwort Sphærocarpus. The result of cultures of the spores of this plant brings out the remarkable fact that on the average two spores in each tetrad give rise to male, and the two other ones to female individuals. This distribution does not occur invariably, but it does so in the great majority of cases, and the discovery is of considerable importance and interest. It is clearly in harmony with, and gives greater precision to, the observations already made by others on the distribution of sex in other liverworts and mosses. In the case of the plant in question, it indicates that the sex of the individual to which the spore will give rise is predestined during the meiotic divisions of the spore mother cell—the divisions in which we have good grounds for supposing that many other characters are segregated and distributed. It will be remembered that it is at meiosis that the nuclear chromosomes are *distributed* between the nuclei of two daughter nuclei, so that their number in each of these nuclei is consequently halved. But the coincidence needs to be utilised with caution, and Prof. Strasburger himself fully discusses the difficulties in the way of generalising too freely.

It is obviously necessary to distinguish clearly between the characters appropriate to the sexual cells (or to the gametophytes) themselves, and those sexual *tendencies* of which they are the bearers. The latter, of course, only declare themselves after fertilisation, when the sex of the particular individual of the next generation which springs from them is declared. Whilst it is quite possible, and in certain cases it can be very plausibly argued, that these sexual *tendencies* are decided at meiosis, it appears to be quite certain that the sexual *characters* must be regarded from a different point of view. Thus, notwithstanding the case of Sphærocarpus, where meiosis seems to determine the segregation of the resulting gametophytes into a pair of male and a pair of female plants respectively, a consideration of any heterosporous plant—as, for example, selaginella, suffices to remind one that here, at any rate, the sexual character of the gametophyte is determined by causes which operate before meiosis supervenes. For the difference can be detected in the sporangia. Still more clearly is the same thing apparent in diœcious plants, where the male and female individuals differ from each other, and thus the character of the gametophytes to which they will severally give rise can be foretold at a much earlier stage in the life-history.

With regard to the segregation of the sexual tendencies the matter is otherwise. Although the questions herein involved are very complex, the evidence at present available seems to indicate that the segregation of the opposing sexual tendencies, where it occurs at all, is achieved at the stage and by means of the mechanism of meiosis. The fact that in the interpretations of sex, from this point of view, there exists a lack of unanimity as to the precise constitution of the male and female gametes does not materially affect the position. Thus the question as to whether maleness and femaleness can be regarded as allelomorphic (or alternative, as regards the constitution of the gametes) characters is independent of the views taken as to the heterozygous character, for example, of the male or the female, and it may turn out ultimately that different organisms behave differently in this respect. In this connection it may be mentioned that the alga *Chara crinita* produces only female plants from its parthenogenetically developing eggs, which contain the half number of chromosomes (haploid), whilst in ants, bees, and wasps the corresponding unfertilised, parthenogenetically developing eggs invariably give rise to males.

Intimately bound up with the question of sex are the various instances of eggs which are able to develop into a new individual in the absence of the normal union with a sperm. Strasburger rightly, as we think, criticises those who would include all these cases under the term parthenogenesis. Examples are known of eggs which possess the full premeiotic number of chromosomes owing to the obliteration of the meiotic phase from the life-history. Fertilisation is always absent in such cases, but it is misleading to speak of this as a parthenogenetic development, seeing that the nuclear constitution of such an egg deviates so fundamentally from that of a normal one. Possibly the term "diploid parthenogenesis" might be employed to meet such cases, though we confess to a preference for the word "parthenapogamy" as being more characteristic.

In dealing with the general question of apogamy, the author emphasises the suggestive fact that species which exhibit this feature commonly possess far larger numbers of chromosomes than allied and normal species, and also that they are characterised by a relatively high degree of variability. These two points appear to us to be highly significant, and to merit a closer attention than they have generally received.

Prof. Strasburger holds stoutly to his views as to the omnipotence of the nucleus in determining the course of development. That is to say, the nucleus is regarded as alone bearing the hereditary substance which he believes to consist of distinct bodies responsible for the characters manifested by an individual. He adheres strongly to the view, advanced by Grégoire, that homologous chromosomes (*i.e.* derived from the male and female parent respectively) pair laterally during the prophase of meiosis, and he discounts the speculations which have been based on mitochondrial and such-like cytoplasmic structures. As regards the interpretation of the nuclear transformations which occur during meiosis, Prof. Strasburger admits that he is influenced by theoretical considerations in arriving at his final conclusions. The views he advocates are not shared by all investigators, although at the present time they are rather widely supported. But the available evidence is hardly sufficient as yet to allow of the matter being brought to a decisive issue, and, indeed, the very same preparations have been differently interpreted by the exponents of the divergent views. It is a pity, perhaps, that this should be so, but it is clearly not an unhealthy condition of affairs when the final conclusion on a question of fact is confessedly influenced by other than objective evidence.

The reader will find many other topics treated in this volume by a master hand. Evidence is given to show that the hybrid *Fragaria virginiana* × *F. elatior,* which in the F_1 generation so exactly resembles the latter (male) parent that its hybrid nature has been doubted, does really arise in this way, but that the Elatior parent is completely dominant. Alternation of generations is touched upon, and the book ends with a suggestive speculation as to how the details of nuclear structure, and in particular the meiotic divisions, have come to exhibit so close a resemblance in the higher plants and animals respectively. It is pointed out that so remarkable a fact cannot be otherwise than pregnant with real significance, especially when we reflect that we seek in vain amongst the more primitive animals and plants for the uniformity which on *a priori* grounds we might, perhaps, have anticipated would be found.

It is impossible, in bringing this notice to a close, to refrain from expressing appreciation for the manner in which Prof. Strasburger has handled the more controversial matter in his book. The invariable courtesy with which he treats the opinions of those who happen to differ from himself might well be copied by some who still appear to imagine that scientific discussion should be conducted on the lines of modern politics. Not the least of the qualities which have endeared Prof. Strasburger to a wide circle of friends, in addition to that scrupulous fairness and consideration which he always shows to others, is the open-mindedness with which he is always ready to accept the result of new discoveries, even when, as he himself says, they may involve the sacrifice of long-cherished views.

J. B. Farmer.

METALLIC ALLOYS.

Leçons sur les Alliages métalliques. By Prof. J. Cavalier. Pp. xix+466. Illustrated. (Paris: Vuibert et Nony, 1909.)

During the last twenty years a systematic study has been undertaken of the properties of alloys, their chemical nature and constitution, and the relations between that constitution and their useful properties. The work has been made possible by the invention of trustworthy pyrometers, by the application of microscopic examination to opaque substances, and by advances in the knowledge of chemical equilibrium. The investigations have in many cases been carried out with an industrial aim, but by throwing light on the chemistry of solid bodies they have contributed largely to the development of pure science. It is true that the whole subject is still to some extent in a state of flux, and much remains to be done in order to explain apparent contradictions, and to remove the uncertainty and provisional nature of some of the conclusions. Nevertheless, it is time to make the fundamental principles of the science of alloys part of the course of training of students of general chemistry. Prof. Cavalier's book shows a pronounced superiority for this purpose over previous attempts, and is one of the manuals which teachers of chemistry may usefully place in the hands of their students. It is based on a series of lectures delivered by the author at the University of Rennes, and is characterised by clearness of thought and of language, logical arrangement, and perfection of balance.

The first part of the book contains a brief general description of the methods of preparation and study of alloys. Ordinary chemical analysis is not dealt with, but proximate analysis, and the still more important methods of microscopic metallography and thermal study are discussed, and the physical and mechanical properties are also considered. The treatment is elementary, and is hardly full enough to help those engaged in research, but it is sufficient for students to obtain some knowledge of the methods of determining the constitution of alloys. No attempt is made to set up a complete classification of alloys based on their constitution, but perhaps this need not be regretted when the artificial aspect of some of the previous attempts at classification is remembered.

The second part of the book contains the special study of certain alloys, and is intended to show by concrete examples how the general methods have been applied in practice, and what results have been obtained. There is no attempt to make this part complete by describing all alloys, the author referring the reader to Guillet's book, "Les Alliages métalliques," published in 1906, for details of those alloys which he has omitted to mention. However, Prof. Cavalier has chosen his examples from alloys presenting some industrial interest, and has passed in review most of the important groups. He has contented himself with a single example of each case met with in a systematic study, arranging his material as far as possible in the order of increasing complexity. Thus the simple case of alloys of gold and silver is taken first. The more complicated diagrams of equilibrium assigned to lead, tin and antimony are next dealt with, and these are followed by the brasses and bronzes, in which so many solid solutions occur. The relation between constitution and useful properties find a striking example in the antifriction alloys, and the iron-carbon alloys, of which the practical importance is fundamental, present difficulties in their study owing to the existence of a labile system, and are taken last.

In the section devoted to special steels the method of describing only a few typical alloys is discarded, and a catalogue of the steels is given with their composition and properties, as if a comprehensive book of reference were being written.

The faults of the book are the faults of a university professor when dealing with a practical subject. As soon as works-practice is touched on, the information is not to be trusted. Thus, in the chapter on the preparation of alloys, a somewhat misleading diagram is given of a melting furnace for crucibles, and the statement is made that the maximum charge for a crucible in such a furnace scarcely exceeds 100 kilograms. To show the inexactness of this, it is enough to mention that at the Royal Mint crucibles containing more than 180 kilogrammes of standard silver have been in use for many years, and even larger crucibles are used in mints abroad.

The merits of the volume have already been sufficiently indicated. It is a pleasure to read the book. It can hardly fail to fascinate many of the students into whose hands it will come as a task, and it will be useful to those engaged in the industries as an aid in understanding the numerous articles and papers on alloys which appear in scientific periodicals every day.

T. K. R.

OPEN-AIR STUDIES AT HOME AND ABROAD.

(1) *The Young Naturalist.* A Guide to British Animal Life. By W. P. Westell. Pp. xv+476. (London: Methuen and Co., 1909.) Price 6*s*.

(2) *Nature.* By J. H. Crawford. Pp. x+242. (London: Swan Sonnenschein and Co., 1909.) Price 5*s*.

(3) *Victorian Hill and Dale.* A Series of Geological Rambles. By Dr. T. S. Hall. Pp. x+160. (Melbourne: Thomas C. Lothian, 1909.) Price 3*s*.

(1) THE distinguishing feature of this survey of the British fauna is its comprehensiveness. With the exception of marine fish, there is no large order that does not come in for comment. The mammals, birds, fresh-water fish, and Lepidoptera—the most popular groups—are allotted most space, and are evidently more familiar to the author than the remainder. In spite of certain drawbacks, of which we shall have something to say, this book is a most suitable handbook for a boy or girl who is interested in animal life. The contents are arranged in ordinal fashion, and no attempt is made to deal with the associations of animals characterising field, moor, or lake, nor are there practical suggestions for the capture, maintenance, or preservation of specimens. There are, however, accounts of the habits and distinctive features of the commoner British animals that should be read with interest by young naturalists, and the wealth of clear photographs makes the book a most attractive one.

In dealing with the more familiar orders, the author's observations are evidently based on personal observation, but one can scarcely hope to extend this enviable acquaintance to all the groups, and accordingly there are occasions when the experience of others has to be drawn upon. Unfortunately, in these instances the authorities relied upon by Mr. Westell are not unimpeachable, and have been the cause of several misstatements. Thus, on p. 456, in speaking of the severing of a limb or part of the body, the author concludes, "This is known as autonomy." We can hardly believe the author responsible for mistaking the second "t" for an "n." But in other cases the authority is clear. On pp. 291–5 there is a description of the structure and life of fish that bristles with misleading or inaccurate statements:—"the fish's gills are its lungs"; "a fish need only open its mouth and the water pours in"; "the heart has two cavities"; "the fins along the back and the stomach are especially useful in keeping the body upright"; "probably the sense of taste and touch are only very dull"; "fishes (with one or two exceptions of tropical fishes) are hatched from eggs which are laid by the parent in very large number." Why the author should have trusted to such information instead of going to first-hand authorities we do not understand. The account of the mollusca contains several mistakes. Pearls are said to be due to "a grain of sand or other hard substance. Cephalopods "have no outside shell, the principal eight-armed Cephalopod is the Argonaut or Nautilus." This confusion is rendered still more distressing by a later note (p. 439), in which the "Paper Nautilus or Argonaut" is called "Nautilus pompilius," whilst the shell of the "common Nautilus" is figured and described as a distinct structure. There is a similar confusion between the acorn barnacle and Lepas, the goose-barnacle. The nomenclature, in fact, is inconsistent. On p. 49 the Linnean system is justified, and yet throughout the book confusion is continually arising through the want of its use. What are flat burying beetles or museum beetles? What is the Noonday Fly? Even Mr. Westell seems to become confused by this absurd nomenclature, for he tells his readers to look for the "brine shrimp" in the sea; and evidently believes in some abstraction called the *real* shrimp (p. 316). But for thorough confusion of thought, take the statements that the Brittle Star "ably practises (*sic*) this remarkable habit (of fragmentation) for it casts away in regular and methodic manner certain parts of its body during its early life," or this one of the house fly, "accused often unjustly of disseminating disease, it seems that according to Sir James Crichton Browne, there is much truth in a good deal of what has been stated."

The style of the author really needs a little chastening. "Vasty deep"; "Denizens of the deep"; "I having made observations upon the insects but not them upon me" (p. 423); "despite the hue and cry which one hears so frequently as to the dense human population that this country harbours," p. 169 (as though humans were a kind of vermin), are a few expressions that should have been cut out. We know how easy is the task of picking out weak places in the work of others, and direct attention to these flaws in a very useful book in the hope that a new edition (which certainly ought to be called for) may be even better than this one. References might then be given, in the text, to the attractive illustrations. This is a very necessary, even an essential matter, for the adder, *e.g.*, is figured on p. 20, and the description of it is not given until p. 276, where no reference to the foregoing figure occurs. The same dislocation of figures occurs in many groups.

(2) Mr. Crawford is an impressionist, and one who shares the Wordsworthian spirit. In these slight word-pictures of east-coast scenery he sketches, in a very dainty and observant fashion, the picturesque features of animal life as seen against the varying background of nature's moods. He believes, and reiterates his belief in, the value of our response to such beauty. He is an artist.

"We think in pictures. We recall in pictures. We remember more than we see. With this aid, to evolve our artistic sense were easy, to add a touch of imagination were not hard. Thus, simply, might the world be made to seem beautiful and life be filled with gladness."

These essays will perhaps not add to Mr. Crawford's reputation, but they will certainly not detract from it.

(3) This little book is mainly a reprint of articles on the geology of Melbourne and neighbourhood contributed to the *Melbourne Argus*, but also includes a survey of the strata round Port Phillip Bay and up country to Ballarat and Bendigo. The bedrock, of Silurian age, is characterised by rough, dark-barked gum-trees, and is economically of great importance for the making of pottery and bricks. The wearing down of this rock has produced the gravel beds in which the gold of the bedrock is found. These gravel beds have also their characteristic flora, the grass-trees. Intersecting these are granitic rocks which have weathered out, and support a flora of native cherries, white-barked gums, and other trees. The vast blue-stone plains have been formed by eruptions of lava emerging through the bedrock, and are distinguished by their grassy, treeless appearance. In addition there are glacial beds in many districts, and cinder beds in a few others, supporting dense forest and forming rich farm land. The descriptions are very clear, and are illustrated by good photographs.

ELECTROMAGNETIC THEORY.

(1) *Anfangsgründe der Maxwellschen Theorie, verknüpft mit der Elektronentheorie.* By Franz Richards. Pp. ix+245. (Leipzig: B. G. Teubner, 1909.) Price 7 marks.

(2) *The Theory of Electrons, and its Applications to the Phenomena of Light and Radiant Heat.* By H. A. Lorentz. Pp. iv+332. (Leipzig: B. G. Teubner; London: David Nutt and Williams and Norgate, 1909.) Price 8 marks.

(1) THE first of these volumes deals with the foundations of Maxwell's electromagnetic theory. The author is careful to point out that it is not a text-book, but a sketch based on lectures delivered to teachers. For this reason the treatment differs somewhat from what may be regarded as the normal method of presenting the subject to students; although in a branch of physics which appeals to a comparatively limited class, it may be doubted whether there are satisfactory grounds for introducing preferential treatment.

At an early stage the author shows how the two fundamental "circuital relations" are connected by means of the principle of least-action. This is an excellent feature, and the proof would probably have produced greater impression had some definite physical picture, such as that adopted by Larmor, been introduced.

In succession, the author treats of static effects in non-conductors, of conduction, and of magnetic effects of currents. The introduction of Stokes' theorem, which is delayed until this stage, might, with advantage, have been introduced much earlier.

Induction is next discussed, and finally there is a chapter on electromagnetic waves, which closes with a brief and rather imperfect treatment of metallic reflexion.

As a whole the book is somewhat disconnected, but it ought to be judged as a collection of monographs, and from this point of view the treatment is clear and good.

(2) Lorentz' book deals with the latest development of the electromagnetic theory. It contains a series of lectures delivered in Columbia University, New York, in 1906, and will be welcomed as his latest views on a subject which owes its origin and much of its development to Lorentz himself.

There are five chapters and a section of notes, which give calculations too elaborate to be included in the text. Chapter i. treats of general principles and the doctrine of free electrons. It is to Lorentz that we owe the view that the free æther is to be regarded as at rest, and that hence phenomena in it are governed by the two "circuital" and the two "solenoidal" equations of Maxwell.

At discrete points we may have electrical singularities characterised by a certain density. The effect of this at those points is simply to make the electric divergence equal to the density, instead of nil, and to add to the displacement current, a portion due to convection of amount equal to the product of density and velocity. At other points in the æther the effects are sufficiently included in the four fundamental equations. It is of importance to notice that this specification imposes a limitation on the internal character of an electron. Thus if an electron is defined as a shell with a surface charge of electricity, its interior must, on the basis of Lorentz' equations, consist of nothing but æther. The limitation carries important consequences, such as prescribing surface conditions.

In this chapter the author discusses the question of electric inertia on the basis of Kaufmann's experiments; but as he again takes up the question more fully in a later chapter, it will be convenient to reserve our observations.

Chapter ii. is devoted to the question of radiation and absorption of heat. Those who have followed the interesting discussion on this matter in the *Physikalische Zeitschrift* recently, will not be surprised to find that Lorentz devotes some space to the question whether the æther and the radiating body, supposed to consist of electronic radiators, can be regarded as a system to which the law of equipartition of energy can be applied. The result of such an assumption is in flat contradiction to observation. As the law of equipartition has never been proved for purely dynamical systems, and is probably not in general true, it is not surprising that it fails when applied to the æther.

The Zeeman effect is discussed in chapter iii., and the author is chiefly concerned in showing how little progress has been made in elucidating the phenomena, and how much knowledge of atomic structure we may reasonably hope to gain from study of the facts.

The electron theory of dispersion is next dealt with. Probably most readers will regret that the author has not found it possible to enter more fully on the problem of the optical properties of metals.

Optical phenomena in moving bodies forms the subject of the last chapter. The explanation of Fresnel's hypothesis on an electromagnetic basis is one of the most important results contributed by Lorentz to optical theory. The explanation of the result of the Michelson-Morley experiment and of the double refraction experiment by Lord Rayleigh and Brace, forms most interesting reading. The hypothesis of a contracted electron is introduced, and with it the question of electric inertia is again raised. The chapter closes with an exposition of Einstein's principle of relativity.

The book is a most fascinating one, and to those acquainted with Lorentz' former memoirs, it is unnecessary to say that it is written with a lucidity that characterises a master hand.

We venture to offer some observations on the view that negative electrons possess an inertia which is entirely of electric origin. It appears to us that the proof requires considerably more support, both on the experimental and on the theoretical side, than it has yet received.

For many purposes it is unnecessary to define an electron further than to say that it possesses a charge. But when we come to the question of inertia we have to define the size and shape of the electron. Surface conditions are, of course, determined by the fundamental equations. We confine attention to the two cases considered by Lorentz, viz., the "rigidly" electrified sphere of Abraham and the contracted electron of Lorentz. It has been claimed that Kaufmann's experiments agree with the spherical electron formula and the view that the ordinary inertia is *nil*. As a matter of fact, his experiments agree very much better with the contracted electron formula, but make the ordinary inertia quite comparable with the electric inertia for slow speeds. Bucherer's experiments also agree with the contracted electron formula, and make the ordinary inertia *nil*, but the speed was not so high as in Kaufmann's experiments. On the theoretical side it must be remembered that both formulæ are derived from the energy of the steady state, using the "quasi-stationary state" principle. This principle has been acknowledged as quite unsound, and it must in general lead to false results, when, as in the present case, any change of velocity is attended with radiation into the medium. We have reason to believe that any change of velocity is accompanied by a redistribution of the charge on the electron, and this in general leads to an expression for the inertia which differs from that obtained by differentiating the energy of the steady state.

We may well hesitate to sweep away the last scrap of ordinary matter from an electron until the proof rests on some principle more convincing than that of the quasi-stationary state.

OUR BOOK SHELF.

Handbook of Marks on Pottery and Porcelain. By W. Burton and R. L. Hobson. Pp. xii+210. (London: Macmillan and Co., Ltd., 1909.) Price 7*s*. 6*d*. net.

This volume supplies a distinct want. Mr. Burton is a practical potter, and the author of numerous works on the history of pottery and porcelain. Mr. Hobson is on the British Museum staff, and there are few men with greater chances of seeing and studying examples of all periods of pottery. The authors, therefore, speak with authority on subjects connected with ceramics, and although they style it a "reliable pocket volume," it is really a valuable and interesting addition to the bookshelves of collectors and students of pottery. Thousands of authentic marks will, of course, not be found in the volume, but those chosen are, on the whole, thoroughly representative, and the elaborate indices make the work of reference easy.

It is interesting to note the influence that one factory had on another, as shown by the marks. The Meissen factory was the father of European porcelain. The Cross Swords from the arms of Saxony, which was used there as their mark, can be seen in Caughley Tournay, Worcester, Derby, and Bristol. Even Meissen itself had in its early days, like so many other factories, marks in imitation of the oriental.

The short descriptions and the introduction are models of Precis writing, giving in a page or two the history of potting in each country. There is a little confusion in the use of the terms "hard and soft." Hard paste is fired at a high temperature, and the glaze is fired at the heat at which the porcelain matures. Soft paste, on the other hand, is fired at a lower temperature, and the glaze at a still lower one. The terms hard and soft have nothing to do with the hardness and softness, as usually understood. So far as the body of the piece of ware is concerned, some hard paste may scratch with a file more easily than soft.

The Oriental section is particularly good. It displays very great care, and is a decided advance on anything of a similar kind that has been within the reach of an ordinary collector.

The scheme of the work takes the reader through the various countries, and the period covered extends from the Middle Ages to about 1850, with a selection of modern marks. It is a very great advantage to have the authors' assurance that none but undoubted marks are illustrated in the volume. Great care seem to have been taken with the dates also, but on page 33 the A. R., the cipher of Augustus of Poland, the patron of Bottger, is given by the author as 1725–40. Most authorities, and with reason, place this mark considerably earlier.

The Races of Man and their Distribution. By Dr. A. C. Haddon, F.R.S. Pp. x+126. (London: Milner and Company, Ltd., n.d.) Price 1*s*. net.

This book gives a description of the various races of mankind as complete as appears to be possible within the compass of a small volume. The physical characters and culture of each race are described as far as it is at present known, and the author has in many cases to confess that the knowledge is, as yet, very incomplete. In the general classification of mankind the character of the hair is taken as a primary feature. The three great divisions of mankind obtained in this way are subdivided according to stature or the shape of the head. Whether this is the ideal method of classification or not, it serves as a basis for the orderly description of the various known races. The description of the supernatural beliefs, weapons, houses, &c., of the Oceanic peoples is especially full and complete.

The latest views on the African races and their relations to each other are clearly set out. The native races of Asia are described, though an unduly large proportion of the treatise appears to be devoted to Indian races. The description of European races is comparatively superficial. So little appears to be known about the physical characters of the native races of the American continent that the author adopts a geographical classification, which makes it somewhat difficult to realise the physical relations of these races to each other. Some of Dr. Haddon's views on the relations of races to each other would be disputed by the latest authorities; for example, the view that the Tasmanians belonged to the same race as the Papuans would hardly, we think, be accepted by Prof. Sollas.

There are ten plates of representative members of leading races, and a very useful glossary of ethnological terms at the end of the book. The value of the book to a beginner in ethnology would have been considerably enhanced if it had contained a few maps. This little book is a welcome contribution to anthropological literature, and contains much valuable and accurate information not otherwise easily accessible.

(1) *Der menschliche Organismus und seine Gesunderhaltung.* By Dr. A. Menzer. Pp. 159. (Leipzig: Quelle and Meyer, 1909.) Price 1.25 marks.
(2) *Unsere Sinnesorgane und ihre Funktion.* By Dr. E. Mangold. Pp. vii+147. (Leipzig: Quelle and Meyer, 1909.) Price 1.25 marks.
(3) *Die moderne Chirurgie für gebildete Laien.* By Dr. H. Tillmanns. Pp. iv+156. (Leipzig: Quelle and Meyer, 1908.) Price 1.25 marks.
(4) *Die Geschlechtskrankheiten, ihr Wesen, ihre Verbreitung, Bekämpfung und Verhütung.* By Prof. Schumburg. Pp. vi+102. (Leipzig: B. G. Teubner, 1909.) Price 1.25 marks.

THESE four little books are examples belonging to two series of publications, which embrace a number of works on religion, philosophy, literature, art, history, geography, science, &c. They give a clear, concise and popular exposition of the various subjects with which they deal. From our insular standpoint in some instances certain subjects are discussed in a more open manner than we are accustomed to.

In the first book on the list, after a brief description of the anatomy, histology, and physiology of man, the various subjects of the causation of disease, infectious diseases, clothing, food, and general hygiene are simply and adequately described.

In the second book, the various organs of the special senses, sight, hearing, smell, taste, and touch, are described, and the mechanism of their action, so far as is known, is detailed. In "Modern Surgery" the reader is introduced to surgical theory and practice as regards the Röntgen rays, anæsthesia, arrest of hæmorrhage, sterilisation and antiseptics, preparation for operation, microorganisms, and their relation to disease, inflammation, burns, wounds, cancer, &c. The book would form an excellent little text-book for nurses.

The fourth book deals in a very outspoken manner with the subject of venereal diseases, their consequences, spread, and prevention. The diseases are briefly described, the various measures of prevention detailed, and the social evils of prostitution and their remedy are discussed. We should consider it hardly advisable to place such a book in the hands of the general educated public, unless the reader had actual need to study the question with which it deals. All the books are clearly printed and freely and adequately illustrated.

R. T. H.

Plant Galls of Great Britain. A Nature-Study Handbook. By Edward T. Connold. Pp. xii+292. (London: Adlard and Son, 1909.)

THIS volume will certainly prove to be of great use to all students of insect and plant life. The author's previous works, viz., "British Vegetable Galls," published in 1901, and "British Oak Galls," published in 1908, are already well known. The present book is intended for the pocket as a guide in the field to botanists and collectors. The descriptions are condensed and brief, but Mr. Connold has not forgotten the value of good illustrations, and each description is accompanied by an excellent and typical photograph of the gall described. As the author points out, the systematic study of all British plant galls is as yet by no means complete. The subject offers a wide and interesting field for further research. This volume is well adapted to create an interest in these interesting vegetable structures, and to encourage the beginner to pursue his studies further.

The opening chapters give ample directions as regards the time when, the place where, and the manner how, to collect and study the various galls. The gall-producers, their habits and the principles of gall formation, are also adequately dealt with.

The list of English and Latin names of the host plants mentioned in the volume will be found of great use in the field. The various nomenclatures are becoming a vexed question, and a useful list of synonyms of gall producers has, therefore, been included, and at the end a very full index is given. The book cannot fail to serve its purpose as a field companion for the practical student of nature.

The Rhodesian Miner's Handbook. By F. P. Mennell. Second edition. Illustrated. Pp. 167. (Buluwayo: Ellis Allen, 1909.) Price 5*s*.

THIS is the latest of a series of books issued from the Rhodesia Museum. They are presumably intended to interest and instruct the settlers in the country, and to promote the prosperity of the industries of Rhodesia. Looked at in this light it may be that the book under review was well worth producing, and will be useful to its readers, but it is of little interest except to a prospector who has had no scientific training. It contains chapters of an elementary character on geology, mineralogy, ore deposits, prospecting, &c., and a quantity of miscellaneous information as to the present condition of the mining industry in Rhodesia. This is divided into sections, under the heads of precious metals, base metals, precious stones, and coal. The relative importance of the industries is indicated by the fact that in 1907 the gold represented nearly 94 per cent. of the total mineral production, and amounted in value to 14*l* 15*s*. per head of the white population, as compared, for example, with about 100*l*. per head in the Transvaal, and 26*l*. per head in Western Australia.

Los Métodos de Integracion. By Carlos Wargny. Pp. 234. (Santiago de Chile: Cervantes, 1907.)

IT is interesting to find that Spanish students in Chile study the integral calculus: otherwise this compilation calls for no special remark. It contains a collection of elementary examples of indefinite integration, many of which are worked out in elaborate detail. On pp. 128–9 Gregory's series and the expansion of arc sin x are given, without proper indication of the limits of the integrals from which they are derived.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Temperature of the Upper Part of Clouds.

AT the recent meeting of the British Association, a report of which appeared in NATURE of October 14 (p. 473), Prof. A. L. Rotch gave an account of the highest balloon ascent in America. It is stated he found the remarkable result that on at least two ascents the temperature increased in a cumulus cloud in passing upwards. It is stated that during the discussion of the paper doubt was expressed as to the reality of the phenomenon. The first thing that strikes one on reading Prof. Rotch's result is that it seems rather curious that this phenomenon had not been recorded in previous ascents. When one considers the conditions, it is only what might be expected. The upper part of the cloud is receiving and dealing with the whole solar radiation falling on its surface, as none of it passes through it. Some of this heat penetrates some distance into the cloud, where it undergoes repeated reflections from the cloud particles. One would thus expect that the cloud particles and the saturated air would absorb some of the heat and have their temperature raised, though probably the greater part of the heat is reflected into space.

There is, however, a point to which I wish to direct attention, and that is to the extreme difficulty of getting anything like correct records of temperature and humidity in the conditions existing at the top of cumulus clouds. On one occasion, while making observations on Pilatus Kulm, the top of the mountain being at the time in dense cloud, but evidently near its upper limit, part of the observations consisted in taking readings of wet- and dry-bulb thermometers, but under the conditions it was found to be very difficult to get trustworthy results. All sorts of abnormal and contradictory readings were at first obtained, even to the wet-bulb reading higher than the dry. A few observations of the surroundings cleared up the difficulties. To begin with, one felt as if in an oven. Radiant heat streamed in from every direction, though no sun was visible, not even the direction of it. An examination of the surfaces of surrounding objects showed them to be in a very abnormal condition, though in the midst of dense cloud many of them were perfectly dry, not the usual dripping condition. The heat reflected from the cloud particles was absorbed by the surrounding objects, and their temperature raised far above the dew point. For instance, a thermometer placed on a large piece of wood showed a temperature of 60° F., while if hung up near it only rose to 48°.

Under the conditions the diffused radiation acted on all surfaces and raised their temperature, but, of course, did not raise them all to the same amount, large bodies, as is well known under these conditions, being much more highly heated than small ones. For instance, ordinary pins driven into a wooden post for hanging the thermometers on got wet, while the post was quite dry. All other freely exposed small objects were wet, and all large ones dry. It was while the thermometers were hung on the post that the wet bulb read higher than the dry, the reason being that the dry was not really dry, but had a film of water over it; and it was colder than the wet bulb, because it was a little smaller, and the wet had also the advantage of a better heat-absorbing surface in its muslin covering. The wet- and dry-bulb temperatures could only be obtained after they had been properly protected from all radiation. In ordinary cloud observations no such protection is required.

As bearing on the question of the heat absorbed by clouds, it may be mentioned that while the observations were being made on Pilatus Kulm the atmosphere was in a constant state of boil, so to speak. Vertical currents were constantly surging up on one side or the other, though there was no wind. These vertical currents were probably due to the disturbing effects of the absorbed heat, and they seem to suggest that this heated upper part of the cloud may explain the formation of those pillar-like clouds sometimes seen rising from sunlit cumulus by the hot part breaking away from the body of the cloud and rising high above it. JOHN AITKEN.

Ardenlea, Falkirk.

Lines of Force and Chemical Action of Light.

THE fact that carbon dioxide is dissociated at the low temperature of the surrounding medium, when green organs of plants are exposed to sunlight, has been often considered as somewhat paradoxical. Count Rumford was the first who tried to account for it by suggesting that this process takes place in spaces so small that the temperature produced by the absorption of light may approach the highest temperatures obtainable in our laboratories. More recently I tried to adduce in support of this ingenious interpretation some considerations, derived from the experimental study of the actual conditions of this photochemical process.[1] Still more wonderful is the possibility of its going on, though very slowly, in diffused sunlight. But perhaps in the whole range of photo-chemical phenomena there is no fact more wonderful than the possibility of obtaining photographs of the remotest star or nebula.

All these photo-chemical riddles seem to me to find their full explanation in Sir Joseph Thomson's theory,[2] so eloquently expressed in his recent presidential address to the British Association at Winnipeg.[3]

If "a wave of light may be regarded as made of groups of lines of electric force," if "in the wave front there cannot be uniformity," and "it must be more analogous to bright specks on a dark ground than to a uniformly illuminated surface," then it becomes evident that the chemical effect of light on a single molecule cannot fall off in the same ratio as the dispersion of light in space. A single molecule lying in the path of a line of force may be, with regard to the distant sun or star, in the same condition as another molecule in the nearest proximity of these centres of energy. It will be only the number of molecules attacked that will be reduced with the increasing divergence of the lines of force, and this result can be compensated by prolonging the exposition. It seems to me that Sir Joseph Thomson's theory furnishes for the first time a real explanation for the fact that a ray of light is not deprived of its photo-chemical efficiency, no matter how great the distance between the source of energy and the molecule acted upon.[4] These considerations may give us perhaps a deeper insight into the part played by radiant energy in the chemistry of the universe than we possess until now.

A full discussion of the problem would require, of course, something more than the very modest scientific equipment of a botanist, and I should be very grateful if a more competent reader of NATURE would find it worth while to decide the question whether the conclusions here deduced are really consistent with Sir Joseph Thomson's theory.

The Position of the Radio-active Elements in the Periodic Table.

MANY arrangements have been suggested, which include the radio-active elements in the periodic table. So far as I am aware, these have all attempted to confine each space in the table to a single element. This restriction has led to unlikely assumptions, on account of the large number of these elements, and the limited number of spaces vacant preceding uranium.

From analogy with organic compounds it seems possible that different internal structures of the atoms of the heavier elements may exist, resulting in elements of the same weight with perhaps very different properties. Similarly, elements with very nearly the same weight might possess very similar properties. This would allow the truth of the following table, in which only three assumptions are made.

[2] "Electricity and Matter." (1903.)

[3] NATURE, August 26, p. 253.

[4] For instance, it seems to me that the following lines, though referring to photo-electric, may be as well applied to photo-chemical phenomena: ". . . thus any effect which can be produced by a unit by itself will, when the source of light is removed to a greater distance, take place, less frequently it is true, but when it takes place it will be of the same character as when the intensity of light was stronger." Sir Joseph Thomson, "On the Ionisation of Gases by Ultra-violet Light, &c." (Proceedings of the Cambridge Philosophical Society, vol. xiv., part iv., p. 421).

(1) It is possible that two elements of nearly the same atomic weight may occupy the same place in the table.

(2) The emission of an α-particle is accompanied by the production of an element which occupies the adjacent space of lower atomic weight.

(3) The emission of a β-particle, or a rayless change, may or may not be accompanied by a remove to a space of lower atomic weight.

In the table the elements which emit α-particles are printed in thick type, the other radio-active elements in italics.

								H 1

← **Ra Em**	←	**Ra** ← 226·5	**Ionium** ←	*UrX*	← **Radio-Ur ?**	**Ur** 238·5		

In considering this table, if we assume that Rutherford and Soddy's theory, that the loss of an α-particle is accompanied by a corresponding decrease of 4 in the atomic weight, is correct, it seems certainly necessary to confine radium and radio-thorium to the same space in the table. They are both members of the barium series. The atomic weight of radium is 226·5, while that of radio-thorium must be (232·5−4)=228·5. Similarly the thorium and radium emanations resemble each other so closely that it is legitimate to suppose that they occupy the same space. They condense at almost the same temperature, while their rates of diffusion into other gases are very nearly the same. If one case is admitted, the whole is rendered probable. The evidence with the actinium series is not so positive, but the present arrangement satisfies the known facts.

It may be pointed out that there are three α-emitting elements between radium emanation and lead, and only three spaces in the table, and two α-emitting elements between thorium emanation and bismuth, with two spaces corresponding; lead and bismuth were suggested by Rutherford and Boltwood as the respective end-products of these series. Again, it may be emphasised that the anomalous existence of the group of rare earth metals, giving a difference of more than 40 in the atomic weight of the elements which precede and follow them, explains the change of the difference between two elements of a vertical series from about 46 to nearly twice that figure, so that no element of the argon series is to be expected between xenon and one with a weight about 220. *Except in the two spaces in the vertical series below manganese*, and possibly in the rare earth series, *there is no vacant space in the periodic table between hydrogen and uranium.* In this connection it is interesting to recall the suggestion of R. W. Wood (Astrophys. Journ., 1908, vol. xxviii., p. 75), that the green line in the spectrum of the sun's corona is the fluorescent line of some common element, and that the supposed element "coronium" of weight less than hydrogen does not exist.

It is possible that other β-emitting or rayless elements may be discovered. How far these are really *elements* depends, of course, on the *specific* physical and chemical properties they possess. These are often none too well defined. The mechanism of a rayless change, or one accompanied by the emission of a β-particle, may be compared with a change of frequent occurrence with organic compounds, the formation of one desmotropic substance from another under the influence of heat.

It must be remembered that should the conclusions be correct which are drawn from the recent work of Ramsay and Gray on the boiling point and critical constants of radium emanation, and should the atomic weight of 176 be confirmed, not only are the above arguments invalidated, but the whole theory of disintegration put forward by Rutherford and Soddy will require modification.

University College, London. A. T. CAMERON.

Radio-activity and the Rocks.

IN the course of some observations which I have recently made with regard to the pleochroic halos sometimes seen round inclusions in various rock-forming minerals, certain points have suggested themselves as possibly of considerable significance. It may be premised that Prof. Joly's suggestion that the halos are due to the α rays emitted by radium appears fully borne out by their remarkable constancy in size and by the fact that they are invariably connected with minerals independently known to be strongly radio-active, that is, comparatively speaking. The only qualification that need be made respecting this view is with regard to the possibility of radio-active substances other than radium producing the observed effects.

So far as my experience goes, the following minerals are capable of producing halos when enclosed in suitable substances like biotite, cordierite, hornblende, tourmaline, &c., zircon, orthite (allanite), epidote, sphene, and apatite. All these are silicates, except apatite, which is a phosphate. The last three are lime compounds, which does not, however, seem to be of any particular import. Zircon contains zirconium, orthite cerium and its allies, and sphene titanium, and it may be noted that orthite always contains thorium in some quantity, while both zircon and sphene may be expected, from a mineralogical point of view, to contain that element as an impurity. Epidote, being isomorphous with orthite, and frequently intergrown with it in rocks, the presence of some traces of thorium may also be generally presumed. As regards apatite, it is obviously significant that the other two phosphates which occasionally occur as rock-formers, namely, monazite and xenotime, always contain thorium in considerable amount; indeed, monazite owes its commercial value to the constant presence of that element. It would appear, therefore, as if the radio-activity of all the minerals cited might, unless other considerations are opposed to the idea, be fairly attributed to the presence of thorium.

There is, however, another feature of these minerals which may be of significance. It will be noticed that one or other of them contains all the elements grouped under carbon in series four of the periodic table, namely, titanium, zirconium, cerium, and thorium. Indeed, "carbonaceous matter" is itself recorded by Prof. Rosenbusch ("Rock-making Minerals," p. 197) as giving rise to pleochroic halos in andalusite. Of course, this might imply nothing more than that chemical similarity leads to similar impurities (*e.g.* thorium), to which the radioactivity may be due. It is not easy to see how such an explanation would fit the case of carbon, but otherwise it would readily account for the fact that halos are not always seen round the minerals mentioned above, and that they may occur round some crystals and yet not round others in the same rock. They are most common, indeed practically constant, round zircon and orthite, but are confined to a few occurrences of the abundant minerals sphene, apatite, and epidote.

Another point which seems to deserve emphasis is the fact that, from a geological point of view, the radioactivity of thorium must surely be a far more potent factor than that of uranium and its derivatives. For there is no mineral which occurs in ordinary rocks which appears to contain uranium in quantities appreciable by chemical methods, whereas, as will be inferred from what has been already said, thorium is of extremely wide distribution.

F. P. MENNELL.

Bulawayo, Rhodesia, October 18.

Magnetic Storms.

IN his letter (NATURE, November 11) Dr. Simpson raises an argument as to the absence of corresponding changes in the electrical potential gradient during magnetic storms which, if admitted, would, I imagine, prove a serious difficulty in the "electron stream" theory of magnetic disturbances. On the assumption that the arriving stream induces an opposite charge which resides at the earth's surface, we can agree with Dr. Simpson's calculation, except that, since there are two current sheets of opposite sign, the potential gradient ought to be half what he finds.

It seems to me most unlikely that the induced charge resides at the earth's surface. The atmosphere is slightly conducting, and it is throughout it that the induced charge distributes itself. It is well known that a very slightly conducting shell will with great rapidity act as a perfect electrostatic screen, but, on the contrary, fails to screen magnetic effects. In his paper (Phil. Trans., A, 1908) on terrestrial magnetism, Dr. Schuster points out that the normal conductivity of air at the earth's surface is about 10^{-24}, while at a height such that the pressure is 1 dyne per sq. cm. the conductivity would be about 10^{-18}. For such a conductivity the time constant of decay would be about 10^{-4} of a second, or, in other words, practically complete electrostatic screening would be established in about one-thousandth part of a second, and correspondingly the slight initial magnetic screening would then cease. We have thus a simple explanation of the absence of direct electrostatic effects at the surface of the earth due to "electron streams" several hundred kilometres above the earth. The earth currents which do accompany magnetic storms are thus referred, not to electrostatic induction, but to change of magnetic induction at the earth's surface.

GEORGE W. WALKER.

Eskdalemuir Magnetic Observatory, November 12.

The Photometric Measurement of the Obliquity Factor of Diffraction.

IN vol. lxxviii. of NATURE (May 21, 1908, p. 55) was published a note on "Secondary Waves of Light," in which I described the diffraction effects produced by an obliquely held rectangular aperture or reflecting surface, and pointed out that the observed distribution of illumination in the pattern was not in accordance with that deduced in the ordinary way. I indicated an explanation of the discrepancy, that it was due to the variation of the obliquity factor of diffraction within the limits of the pattern.

The interest of the observations lay in the fact that such an effect had never been noticed before, and that the observations enabled us actually to trace the variation of the amplitude of vibration from point to point on Huygens's secondary waves. A full description of the effect and a mathematical investigation were published in the *Philosophical Magazine* for January.

The effect observed was that the intensities of illumination in corresponding bands on opposite sides of the central band in the unsymmetrical pattern were unequal. A photometric investigation of this difference in illumination has been carried out. The method was to use revolving sectors to reduce the illumination in one of the two bands to be compared, so as to make them both of equal brightness. The following table illustrates the comparisons made:—

No. of expt.	Ratio of illumination according to ordinary theory	Ratio of illumination actually determined	Ratio of illumination calculated from obliquity
1	... 1·00	... 1·66	... 1·61
2	... 1·00	... 1·81	... 1·98
3	... 1·00	... 2·66	... 2·43
4	... 1·00	... 3·25	... 3·27

The obliquity law demonstrated by these measurements is that, in the hemispherical wavelets emitted by each element of a transmitting aperture or reflecting surface upon which waves are incident at any angle, the amplitude of the light vector is, at any point in the plane of incidence, proportional to the cosine of the angle made by the line joining that point and the element, with the normal to the plane of the element.

Mendelian Heredity: A Correction.

I SHOULD be glad of an opportunity of correcting the following errors in my book "Mendel's Principles of Heredity":—

On p. 35, Davenport's result regarding rumplessness in fowls is accidentally inverted. The character, according to him, is recessive, not dominant as stated by me. I have to thank Prof. Arnold Lang for this correction.

The other, and more serious, error is in the description of Fig. 34 of the second impression of the book (p. 231). In giving a tentative scheme for the descent of colour-blindness, I there stated that a male homozygous for colour-blindness could be produced by the mating of two colour-blind parents; but if the scheme is right, it evidently follows that such a male cannot be formed even from that mating.

The Functions of the Martian Canals.

WITH reference to the recent paper by Dr. Pocklington before the Royal Society, on the functions of the Martian canals, a notice of which appeared in NATURE of November 11 (p. 58), I should like to suggest that these canals may perhaps be used for power-storage purposes. In Mars, possibly, there are seasons of winds or monsoons during which the upper reaches of the canals would be pumped full by innumerable windmills, and the power thus stored utilised during calm seasons, and transmitted electrically for lighting, heating, and general power purposes. For a population which had exhausted all its mineral fuel, which possessed no extensive ocean, and whose soil and climate were unsuitable for the growth of fuel, this would indeed appear to be the only means of obtaining heat and power. The same canals could serve the triple purposes of communication, power, and irrigation.

[1] "Survey of India: Professional Paper, No. 10. The Pendulum Operations in India, 1903–7." By Major G. P. Lenox-Conyngham, R.E.; with an appendix by A. Strahan, F.R.S. Pp. ix+196. (Dehra Dun, 1908.)

"Deutsche Südpolar Expedition, 1901–3." Band i., Geographie; Heft iii., Die Schwerkraftsbestimmungen der Deutschen Südpolar Expedition. By E. von Drygalski und L. Haasemann. Pp. 285–363. (Berlin: Georg Reimer, 1909.) Price 12.80 marks.

Prussian Geodetic Institute and of the Central Bureau of the International Geodetic Association. The same chief directs them both, and a visitor sees no obvious line of demarcation between the two. There is, however, no need to inquire minutely how much is Prussian and how much is international; the resources and experience of both are freely available when advice and cooperation are desired.

The last series of pendulum operations in India had been brought to a close in 1871 with the tragic death of Captain Basevi, who lost his life from exposure while working with the Royal Society pendulums at great altitudes in the Himalayas. When the Government of India resolved to undertake a new and more extensive series, they began by asking the advice of Prof. Helmert, chief of the Central Bureau. He recommended the use of half-second pendulums of the von Sterneck pattern, offered to obtain them from the makers in Vienna who had supplied the Potsdam instruments, and to standardise them at Potsdam. In 1902 Major Burrard and Captain Lenox-Conyngham went to Potsdam to study the use of the pendulums, and Prof. Haasemann, to whom the standardisation had been entrusted, gave up the whole of his time to their instruction. The pendulums were then swung at Kew and at Greenwich, were taken to India, and set to work; and, lastly, it was arranged that Dr. Hecker, of Potsdam, returning from his second "gravity-voyage," should join the Indian pendulum party wherever they might happen to be, and swing his Potsdam pendulums in India, to provide a final control of the circuit Potsdam—Kew—Dehra Dun—Potsdam.

The admirable results of this cooperation are visible on every page of Major Lenox-Conyngham's memoir. He started with an equipment already well tried. He could face the peculiar difficulties of Indian pendulum work with the confidence that he knew all about the ordinary troubles; and, by no means least, he can describe his work in a way which makes it perfectly easy to read in conjunction with German work, for they are written in the same language, though in a different tongue.

It is well known that an exceptional difficulty has embarrassed the survey of India for many years. How much does the enormous mass of the Himalayas and the Tibet plateau to the north, how much does the enormous deficiency of mass in the deep ocean to the south, affect the direction of gravity in India? India was the birthplace of Pratt's celebrated hypothesis of "compensation." The general principle, that an excess of matter above the sea-level is compensated by a deficiency of density below, has been established in the Caucasus and the Tyrol. The fact that gravity is normal, not deficient, over the deep oceans was strongly suggested by Faye when he showed that on solitary islands gravity is in excess by an amount corresponding to the mass of the island above the ocean floor; it has recently been established by Dr. Hecker's elegant application of Mohn's method—the comparison of the mercurial barometer and the boiling-point thermometer at sea.

Only in India has the establishment of the principle of compensation suffered a series of small reverses. Colonel Burrard's series of latitude determinations, published a few years ago, showed that a hidden chain of excessive density runs parallel to the Himalayas to the south, which very much complicates the situation. Major Lenox-Conyngham's pendulums confirm the existence of this chain, and bring to light a new feature—that between it and the Himalayas there is a "ditch" along which gravity is in defect; and, lastly, along the fringe of the mountains their attraction is by no means completely compensated. Five stations in the Himalayas and two in the Baluchistan hills were occupied. "At all these points a deficiency of density is revealed, but in no case does it amount to total compensation. . . . Under all the submontane and mountain stations there appears to be a deficiency which is nearly constant in amount, and is not proportional to the height of the station."

But these interesting results touch only the fringe of the Himalayas, and they are not to be taken as indicating a general failure of complete compensation for the mountain mass as a whole. Before this can be either affirmed or denied it will be necessary to get observations further north; and it is interesting to note that, as Major Lenox-Conyngham points out, it is more important to get well in among the mountains than to climb to excessive altitudes, where the conditions make accurate work almost impossible. Unfortunately, access to Tibet is forbidden to British subjects, including its own scientific servants, by the Indian Government; nor is it easy to disguise a pendulum equipment as a praying-wheel.

The technical details of modern pendulum work are highly interesting, in particular the correction for the flexure of the pendulum support. The present practice is a development of Captain Kater's method of the inverted pendulum initially at rest, which is set swinging by the motion of the stand. In its actual shape it is the invention of Prof. Schumann, of the Prussian Geodetic Institute. An auxiliary pendulum is mounted with its knife-edges parallel to those of one of the set; it has an adjustable weight on the bob by which the times of vibration can be made equal. If one is set swinging, the pull of its knife-edges on the agate plates will rock the stand and set the other swinging; over a considerable range the ratio of the amplitudes of the driven and the driving pendulum increases proportionally to the time, and a simple relation connects this ratio with the virtual increase in the length of the pendulum due to the flexure. It is thus a simple matter to determine the correction for flexure of the stand and pillar at each station, and a pretty illustration of the need of the correction is given by those series which were begun upon a concrete pillar newly cast, and show unmistakably the gradual stiffening of the pillar as the concrete hardened.

The pendulum observations are differential, and it is necessary to choose a base. Kew Observatory was selected, because it had been the base for the earlier Indian series, and the National Physical Laboratory gave valuable assistance in the observation of the base series and a re-determination of the constants of the pendulums for verification. At the suggestion of the Astronomer Royal, Greenwich was chosen as a secondary base. A remarkable feature of the report is the exhaustive appendix by Mr. A. Strahan on the geological strata underlying Kew and Greenwich, and their height above the "Palæozooic floor." With these refinements of observation and discussion the observed differences in the value of *g* at Kew and Greenwich become fairly accordant with the theoretical differences, and warrant the conclusion that "henceforward the pendulum may prove as satisfactory in practice as it has always been attractive in theory."

Dr. Drygalski's Antarctic expedition had the bad fortune to be frozen in just outside the Antarctic circle, and he was unable to reach Antarctic land. His pendulum operations were therefore confined to the island of Saint Vincent in the Cape Verdes, to Kerguelen Island, and to a station on the ice near the winter quarters of the *Gauss*. At the two former gravity was in excess, as is usual on oceanic islands; upon the ice it was nearly normal, which confirms the results of Dr. Hecker's recent determinations of gravity at sea. The observations on the ice were of the heroic order, from difficulty, not with the pendulums, but with the clocks. An ice pillar proved nearly as stable as concrete for the pendulums, but the chronometer stopped at a temperature of −35° C., and the clock was filled with snow in the rather inadequate observing hut. The clock was then removed to the ship and connected with the "flash box" by cable; but the ship heeled over in an Antarctic gale, and again the clock stopped. Finally, after six months' work, it was installed in an ice house, when it went creditably.

The discussion of the observations, largely due to Prof. Haasemann, is full of interest, but the interest lies, unfortunately, in the details of the struggle against adverse circumstances rather than in the wealth of results. It is much to be regretted that Dr. Drygalski's pendulums failed to reach land within the Antarctic circle, for it may be long before so complete an equipment and so accomplished an observer travels again to that sector of the Antarctic.

A. R. H.

A NEW OCEANOGRAPHICAL EXPEDITION.

THE *Times* of November 9 announces the organisation of an important expedition for the investigation of the eastern part of the North Atlantic Ocean, with a possible extension westward to Newfoundland. By an Order in Council, dated October 16, his Majesty the King of Norway has granted permission, subject to certain conditions, for the Norwegian Government steamer *Michael Sars* "to be placed gratuitously at disposal for a scientific expedition in the Atlantic Ocean from the Canary islands to the Færöes, in the spring of 1910, proposed by a British subject, Sir John Murray," and also for "the Fishery Director, Dr. Hjort, Assistant Koefoed, and Mr. Helland-Hansen, as well as the ship's captain and engineer . . . to take part in the expedition while continuing to draw their salaries."

The *Michael Sars* is to sail under the Norwegian flag during the expedition, which is to extend over not more than four months, and Sir John Murray has undertaken to pay all expenses not provided for by the Order in Council.

The chief purpose of the forthcoming expedition, which must necessarily contribute results of first-rate importance to the science of oceanography, is to apply the new instruments and methods of research developed during the last few years, more particularly by the International Council for the Study of the Sea, to the deeper regions of the open ocean. It is believed that the use of large nets and trawls is practicable in deep water, and that, should this prove to be the case, zoological discoveries of great interest and importance will be made. The application of methods of high precision to the determination of the temperature and salinity of sea water has yielded results which have raised considerable doubt in the minds of some investigators as to the validity of the earlier observations made by the *Challenger* and other expeditions, and the cruise of the *Michael Sars* should not only afford much entirely new information, but provide a means of valuing the earlier work. Specially valuable data may be expected from the use of Ekman's new current-meter, which makes it possible for the first time to obtain direct measurements of the currents in the depth.

THE REV. W. H. DALLINGER, F.R.S.

IN the history of "Protozoology"—a department which has advanced of late so rapidly that it has journals, laboratories, and professorial chairs devoted to it—an honoured place, in one of the earlier chapters, must be given to the late Dr. Dallinger, for to him and to his fellow-worker, the late Dr. Drysdale, we owe the first complete record of a complex Protistan life-history, and at the same time a fine example of careful investigation.

William Henry Dallinger was born in 1842 at Devonport. He entered the Wesleyan ministry in 1861, and travelled various circuits, much esteemed as an impressive and weighty preacher. A serious illness is said to have driven him from theology to biology, for in his convalescence he took up the study of open-air natural history, and became fascinated with microscopic work. In 1880 he was appointed principal of the Wesley College, Sheffield, but he resigned this position in 1888 to devote himself more exclusively to scientific work, the Wesleyan Conference allowing him to retain his status and prerogatives as a minister, though without pastoral charge or any other office. Dallinger did much effective work as a lecturer on the staff of the Gilchrist Educational Trust, and his popular lectures on such subjects as "The Infinitely Little," "An Hour with the Microscope," and "Spiders," were models of clear exposition. He had a vivid and careful style, and give his delighted audiences a sound mixture of accurate facts and suggestive ideas. A good instance was the lecture on "The Lowest and Smallest Forms of Life," which he delivered on the occasion of the Montreal meeting of the British Association in 1884. For many years Dr. Dallinger was secretary of the Royal Microscopical Society, and he occupied the presidential chair from 1883 to 1887. He took a great interest in this society and in its valuable journal. It is said that during his presidency he travelled to attend the meetings a distance equal to about half the circumference of the globe, and it was characteristic of his conscientiousness that he usually journeyed back from London to Sheffield by the early mail train so as to be in time for his college duties in the morning.

Dallinger's scientific work began about 1870, and in 1873-6 he published, along with Drysdale, a series of papers on the life-history of monads in the *Monthly Microscopical Journal*. The characteristic feature of the patient labours of the two friends was continuity of observation. By means of a delicate mechanical stage and other devices they were able to keep their eye on one particular specimen of *Bodo saltans*, or whatever the flagellate might be, and follow it from phase to phase. By using a binocular they were able to change places without losing sight of the particular creature the life-cycle of which was being traced. On one occasion Dr. Dallinger kept up continuous observation for nine hours. The result was that some complete life-histories were worked out—spore-formation, growth of spores into flagellates, repeated fission of flagellates, conjugation, encysting, and spore-formation again. This was interesting in itself, it was prophetic of much that has followed in recent years, and it exposed one of the pitfalls in which believers in present-day abiogenesis are apt to come to grief.

In connection with the spontaneous generation question—which has had so many fruitful results—Drysdale and Dallinger made some interesting studies, showing, for instance, that although boiling the water killed monads in an active condition, it did not kill the spores. For the spores, indeed, the fatal temperature is very much higher, up to 268° F.

in water, up to 300° F. or more when dry. This led on to one of Dallinger's best known researches (Proc. Roy. Soc., xxvii., 1878), in which he showed that flagellates could gradually adapt themselves to tolerate extremely high temperatures. Starting with a medium at 60° F., in which three selected species (*e.g. Dallingeria Drysdalei*) flourished, he very gradually raised the temperature to 158° F., without killing off the organisms. That scalding heat would, indeed, have been fatal to the original stocks, but there had been, of course, myriads of generations, and the power of resistance to heat had been gradually augmented. The adapted forms showed marked vacuolation. Dallinger seems to have thought that this was a case of the inheritance of "acquired characters," but it is obviously out with Weismann's category of "somatic modifications." It is interesting to recall that Darwin was much interested in Dallinger's experiment because of its bearing on the adaptation of living creatures to hot springs. He wrote:—"The fact which you mention about their being adapted to certain temperatures, but becoming gradually accustomed to much higher ones, is very remarkable. It explains the existence of algæ in hot springs."

So far as we know, Dallinger's microscopical studies did not extend beyond monads and the like except by way of recreation, and his output of work was not great. It was thorough, however, as the man himself, and the lesson of his patience has still to be learned by some of the too impetuous workers of to-day. In 1886 he published the "Fernley Lecture" on "The Creator, and What we may Know about Creation," and he wrote many scientific articles for the *Wesleyan Methodist Magazine*. He wrote also a number of papers on spontaneous generation and heterogenesis, both of which he profoundly disbelieved in, on the ultimate limit of microscopic vision and kindred questions, and on the thermal death-point of microbes. A characteristic deliverance was an address to the Literary and Philosophical Society in Liverpool entitled "Life-histories and their Lessons: a Defence of the Uniformity and Stability of Vital Processes as Controlled by the Laws of Evolution." But his *magnum opus*, apart from monads, was his edition and re-edition (1891 and 1901) of "Carpenter's Microscope," which he brought up to date, and with the aid of specialists developed into a most valuable encyclopædia of the whole science and art of microscopy.

Dallinger was elected a Fellow of the Royal Society in 1880, and he received the honorary degrees of LL.D. from Victoria University in 1884, of D.Sc. from Dublin in 1892, of D.C.L. from Durham in 1896. He enjoyed the respect and esteem of scientific workers, and he has left his successors a pattern of thoroughness, patience, and enthusiasm.

THE STUDY OF GERMAN IN SCHOOLS.

TWELVE months ago an influentially signed letter, dealing with the study of German in secondary schools, was sent to the President of the Board of Education. That letter pointed out the serious neglect into which the study of the German language is falling in secondary schools, and urged the Board to take steps to encourage and foster the teaching of German. It was made clear that the decline of German as a secondary-school subject is a matter of grave national importance from the points of view of general literary culture, the public services, practical utility, and of rendering a good understanding between the peoples of two great nations less easy.

About six months after the receipt of this letter, the Board of Education issued a memorandum (circular 705) on language-teaching in State-aided secondary schools in England, in which an optimistic view of the condition of German teaching in England was taken, and it appeared to be argued that an advance was in progress in the number of pupils studying the language.

The various associations interested in the teaching of modern languages have had the Board's circular in particular, and the whole question generally, under consideration again, and a second letter has been sent to the President of the Board of Education, signed by representatives of the Modern Language Association, the Society of University Teachers, the Teachers' Guild of Great Britain and Ireland, and the British Science Guild.

The letter conveys the sense of disappointment of the associations generally with the "Memorandum on Language Teaching in Secondary Schools in England" (circular 705), and dissents in particular from several of the doctrines and statements laid down in it. It appears that

> The Board of Education has not obtained, and cannot obtain, the materials required for making the return on the time allotted to modern language teaching in schools in the exact form that the motion in the House of Lords made on February 5, 1908, demanded, but there seems no good reason why the Board should not furnish Parliament and the public, in whatever shape it thought good, with the information suggested by the motion. What we desire to know, and what the Board has full power and opportunity for ascertaining, is the present condition of modern language teaching in secondary schools, the place assigned to it in the curriculum by headmasters and governing bodies, the relation in which it stands to the teaching of Classics and of English, the qualifications, emoluments, and status of its teachers. On these points the memorandum throws no light.

The remark in the Board's memorandum that "the advance in the study of German is not at the present moment as rapid as the advance in the study of French, or even of Latin," scarcely represents the facts. All the evidence available shows that, not only has there been no advance in the study of German, but rather a rapid and decided retrogression. Sympathetic action is required to arrest this decline.

The letter continues:—

> As regards the contention that "the curriculum of schools is necessarily guided by the course of the Universities to which it is to lead," we would observe that only a fraction of the pupils in State-aided schools proceed to the university, and no curriculum can be deemed satisfactory which does not satisfy the needs of the bulk of the scholars. The majority of the pupils in these schools leave school before the age of seventeen, and it is allowed that for such pupils, "both practically and educationally, German is a language of the first importance"; yet the Board throws the whole weight of its influence into the scale of Latin as against German, apparently out of consideration for the one boy in a hundred who will go on to the university; and in this case what would be confessedly good for the many would be no less good for the favoured few. The number at Oxford and Cambridge taking medicine, science, and modern subjects is rapidly on the increase, and it is a constant cause of complaint among the professors and teachers of these subjects that their pupils come to them heavily handicapped by their ignorance of German. It is hardly necessary to insist on the value of a knowledge of German to honour students in every faculty.
>
> Our suggestion that the Board should encourage and foster schools of the type of the German Realschule and Ober-Realschule is not noticed, but it is indirectly negatived by the insistence on Latin as one of two foreign languages where two are taught.

We would reiterate our conviction that a sound and thorough literary training can be given through English, German, and French without a knowledge of Latin. If, in the words of the memorandum, English can serve as "the backbone of a humanistic education," surely a combination of English, German, and French would constitute a valuable type of humanistic education.

We greatly regret that the Board has not, as yet, seen its way to lead public opinion on so vital a matter as the study of modern languages, and we express a hope that the memorandum is not its last word.

NOTES.

THE following is a list of those to whom the Royal Society has this year awarded medals. The awards of the Royal medals have received the King's gracious approval:—the Copley medal to Dr. G. W. Hill, For.Mem.R.S., for his researches in mathematical astronomy; a Royal medal to Prof. A. E. H. Love, F.R.S., for his researches in the theory of elasticity and cognate subjects; a Royal medal to Major Ronald Ross, F.R.S., for his researches in connection with malaria; the Davy medal to Sir James Dewar, F.R.S., for his researches at low temperatures; and the Hughes medal to Dr. R. T. Glazebrook, F.R.S., for his researches on electrical standards.

WE regret to see the announcement of the death, on November 12, of Dr. W. J. Russell, F.R.S., in his eightieth year.

THE death is announced, at sixty-six years of age, of Sir William Thomson, C.B., honorary surgeon to the King in Ireland, and the author of several publications on surgical subjects.

SIR T. H. HOLLAND, K.C.I.E., F.R.S., professor of geology and mineralogy in the Manchester University, will deliver the Wilde lecture of the Manchester Literary and Philosophical Society for 1910.

THE death is announced, on November 13, of Dr. C. Graham, formerly professor of chemical technology at University College, London, at seventy-four years of age. Dr. Graham was a vice-president of the Institute of Chemistry in the years 1882–4, and served on the council for several years.

THE specimens illustrating the manufacture of high-class lenses, shown by Messrs. J. H. Dallmeyer, Ltd., at the Franco-British Exhibition last year and the Imperial International Exhibition this year, have been presented to the Board of Education. This collection, which was awarded a Grand Prix, is now housed in the western galleries of the Science Museum, South Kensington.

AT the annual general meeting of the Cambridge Philosophical Society on October 25, the following were elected officers of the society for the ensuing session, 1909–10:—*President*, Prof. Bateson; *vice-presidents*, Dr. Hobson, Dr. Fenton, Prof. Seward; *treasurer*, Prof. Newall; *secretaries*, Mr. A. E. Shipley, Dr. Barnes, Mr. A. Wood; *new members of the council*, Sir J. Larmor, Prof. Biffen, Prof. Pope, Mr. R. H. Rastall, and Mr. K. Lucas.

AT the annual general meeting of the London Mathematical Society on November 11 the following were elected as the council and officers for the session 1909–10:—*President*, Sir William Niven, K.C.B., F.R.S.; *vice-presidents*, Mr. A. Berry, Dr. W. Burnside, F.R.S., Major P. A. MacMahon, F.R.S.; *treasurer*, Sir Joseph Larmor, F.R.S.; *secretaries*, Dr. A. E. H. Love, F.R.S., Mr. J. H. Grace, F.R.S.; *other members of the council* (names of members not on the retiring council are in italics), Dr. H. F. Baker, F.R.S., Mr. G. T. Bennett, *Dr. T. J. I'A. Bromwich, F.R.S., Mr. E. Cunningham,* Mr. A. L. Dixon, Dr. L. N. G. Filon, Dr. E. W. Hobson, F.R.S., Mr. H. W. Richmond, and Mr. A. E. Western.

SIR ERNEST SHACKLETON was officially received by the Paris Geographical Society on Monday, November 15, in the Grand Amphitheatre of the Sorbonne, and gave an account of his Antarctic expedition. From the *Times* we learn that after the address Prince Roland Bonaparte, the president of the society, rose and said:—"Since its foundation in 1827 our Geographical Society, which is the *doyenne* of all similar societies, has always desired to recognise the labours of the most illustrious travellers by bestowing upon them its grand gold medal. Among those to whom it has been given were the Polar explorers Sir John Franklin, Sir James Clark, Ross, Dumont d'Urville, and Nansen. To the list of these great names the Geographical Society is happy to add yours by offering you its grand gold medal, which is the highest recompense that is in its power to bestow."

THE first session of the seventeenth International Congress of Americanists will be held in Buenos Ayres, Argentine Republic, on May 16–21, 1910. The general and sectional meetings will be held in the hall of the National University in Buenos Ayres. A second session will take place in Mexico in September of the same year. A commission of organisation has been formed, the president of which is Dr. José Nicolas Matienzo, dean of the faculty of philosophy and letters in the National University. Communications, which may be either oral or written, may be made in English, French, German, Italian, Portuguese, or Spanish. The conference will deal with questions relating to the ethnology, archæology, and history of the New World, and a detailed programme will be published towards the end of the present year. For further information application should be made to the general secretary of the committee of organisation, Dr. Lehmann-Nitsche, Calle Viamonte 430, Buenos Ayres.

THE annual report of the Liverpool Marine Biology Committee and the Port Erin Biological Station was submitted by Prof. Herdman at a meeting of the Liverpool Biological Society on November 12. In the course of his address Prof. Herdman gave an account of the work, both scientific and economic, carried out during the past year, such as the curator's report upon the hatching and setting free of more than seven millions of young plaice, making a total of $25\frac{1}{2}$ millions during the six years the hatching has been in operation; the experiments in lobster rearing; Dr. Ward's investigations on the eggs and young larvæ of the plaice (illustrated by many very beautiful enlarged photographs); Mr. Gravely's work on the development of the brittle-starfish; Dr. Herbert Roaf's researches on digestion in marine animals; Mr. Dakin's physico-chemical observations on the condition of the sea-water at different times in connection with the migrations of the food of fishes; Mr. Edwin Thompson's photomicrographs of various types of minute organisms in the sea; and Prof. Herdman's own investigations into the detailed distribution of life in the sea. Some of the biological stations and establishments for fish culture in Canada and the United States were also described, and attention was directed to the American system of providing dormitories and dining halls for the students and researchers, and to the manner in which men of wealth in the States advance science by making large donations to such laboratories in order to defray the expenses of special investigations or marine and other explorations.

DR. D. S. JORDAN, president of Stanford University, contributes to *Science* an appreciation of the work of Dr. Kakichi Mitsukuri, dean of the college of science in the Imperial University of Tokio, who died on September 16. Dr. Mitsukuri was the author of numerous papers on zoological subjects, and was largely responsible for the establishment of the seaside laboratory at Misaki, where much excellent work has been done by Japanese, as well as by American and European naturalists. Dr. Mitsukuri was born in Edo, Japan, on December 1, 1857. He went to America in 1873, and received the degree of Ph.D. in zoology from Yale University in 1879. Returning to Japan, he was appointed a professor of zoology, in 1882, in the science department of the University of Tokio. In 1883 he received the degree of Ph.D. in zoology from Johns Hopkins University. In 1893 he was appointed councillor of the Imperial University. In 1896 he was made head of a commission for the investigation of the fur seal, and in 1897 he signed on behalf of Japan a treaty whereby Japan agreed for a certain length of time to consent to any adjustment of this matter which might be made by Great Britain and the United States. Dr. Mitsukuri was made dean of the College of Science of the Imperial University of Tokio in 1901, and six years later was awarded the Order of the Sacred Treasure in recognition of his public services. Of late years Dr. Mitsukuri was engaged in the special study of the turtles, and was also largely occupied with matters of administration.

TWENTY-FOUR delegates, representing Great Britain, France, Germany, Austria-Hungary, Russia, Spain, United States, Canada, and Australia, met at the Foreign Office on Tuesday to consider the steps to be taken for constructing a map of the world on the scale of 1 : 1,000,000 (16 miles to the inch), on a uniform system. The conference was opened by Sir Charles Hardinge, Permanent Under-Secretary of State for Foreign Affairs. In opening the congress Sir Charles Hardinge summarised the history of the movement. The *Times* reports him to have said that it was in the year 1891 that the question of an international map was first raised at the International Geographical Congress at Berne. Two years later several distinguished German men of science met at Stuttgart, where the question was again seriously discussed, and upon that occasion Prof. Brudener contributed a very valuable report upon the subject. Two years later the matter was taken up by several geographical societies both in Paris and London, and it was fully discussed at a meeting of the Geographical Congress in London in 1895. In various countries the preparation of maps on the scale of 1 : 1,000,000 was then commenced. These maps were chiefly of Asia and Africa, and though uniform in size, sheets, and scale, were wanting in uniformity in other details. The next step of any importance took place in 1908, when it was proposed by the delegates of the United States of America, at the International Geographical Congress at Geneva, that an international map should be definitely standardised. This was agreed to by the members of the congress, and a system of detailed resolutions was universally voted by them. It was felt, however, that unofficial proceedings of this description had no positive result, and were somewhat of the nature of pious aspirations. It was considered necessary, therefore, that the Governments interested should invite official delegates to meet in conference and to arrive at an agreement, which they would be able to submit to their respective Governments for approval and adoption.

THE greater portion of the combined first to fifth parts of vol. xviii. of *Actes de la Société scientifique du Chili* is devoted to an article, by Mr. C. E. Porter, on myriopods, which concludes with a classified list of the known Chilian species.

IN order to obtain sufficient material for an inquiry as to the degree of variation in the wings of beetles of the family Carabidæ, Dr. Sharp asks in the November number of the *Entomologist's Monthly Magazine* for fresh and unmounted specimens of these insects. The inquiry, it is stated, promises to yield results of considerable interest.

AMONG other articles included in the August number of the Annals of the Transvaal Museum, attention may be directed to a check-list of the butterflies of the Transvaal, with notes on certain species, by Mr. C. J. Swiestra. The author has been enabled to raise the number of known species from the 238 or 239 (for both these numbers are mentioned), recorded by Mr. W. L. Distant in 1898, to 316.

IN the October number of the *Museums Journal* Mr. H. Bolton directs attention to a representative series of insects recently installed in the Bristol Museum with the object of displaying the essential features and character of the different orders and their mutual relations, while in a second article the same author emphasises the value and importance attaching to exhibits of injurious insects.

WE have to acknowledge the receipt of the *Scientific Monthly* for October, containing abbreviated reports of some of the presidential addresses at the Winnipeg meeting of the British Association; also of part i. of a catalogue of books on natural history offered for sale by Mr. Quaritch, of Grafton Street. This part includes scientific voyages and the publications of learned societies.

CONSIDERABLE interest attaches to the account, by Mr. C. W. Gilmore, of a new generic type (*Opisthias rarus*) of rhynchocephalian reptile from the Jurassic of Wyoming, published as No. 1698 (vol. xxxvii., pp. 35–42) of the Proceedings of the U.S. National Museum. The genus is established on the evidence of a left dentary bone of the lower jaw, which appears to approximate to the corresponding element in the existing Sphenodon and the Kimeridgian Homœosaurus. Opisthias is the first terrestrial rhynchocephalian hitherto obtained from American strata.

WE have received a copy of the report on the scientific investigations of the Northumberland Sea-fisheries Committee for 1908–9, from which it appears that additional trawlings have been conducted in order to standardise the previous results. A number of marked fish—notably a turbot, after four years—were recovered, while, out of 100 lobsters marked in 1907, thirty-six, none of which had migrated from their native grounds, were re-taken within nine months. An account of the marine laboratory opened at Cullercoats in 1908 is appended. The committee strongly recommends the establishment of a close time for crabs from October to January, during which period many of these crustaceans are changing their shells and out of condition.

TO Mr. W. B. Helland-Hansen, the author, we are indebted for a copy of a report on a recent statistical research into the biology of the cod and the haddock in the North Sea, published in vol. x. of "Rapports et Procès-verbaux du Conseil international pour l'Exploration de la Mer," 1909. The report is based on trawlings carried out to a great extent for the purpose of ascertaining the individual dimensions and weights of the haddock and cod frequenting the fishing-grounds at different seasons and in different years, in order to determine whether the grounds are being over-fished. The investigations are, however, only in a preliminary stage, and before they can be regarded as anything like complete will have to be extended so as to embrace surface-fishing at seasons when the cod are in pursuit of the shoals of herrings.

Our knowledge of Peruvian barnacles has been but slightly increased since the appearance of Darwin's monograph, and considerable interest attaches, therefore, to the report, by Dr. A. Pilsbry, published as No. 1700 of the Proceedings of the U.S. National Museum, on a collection recently made by Dr. R. E. Coker and Dr. W. H. Jones, of the U.S. Navy. The apparent absence of parasitic species or of forms commensural on crabs is a remarkable feature of the cirripede fauna of Peru. A new species of Balanus is described, and the opportunity has been taken to publish figures sufficiently large to exhibit the details of the plates of the previously known Peruvian forms.

In Bulletin No. 67 of the U.S. National Museum, comprising 135 pages of text and a large number of illustrations, Mr. Nathan Banks supplies entomologists with very full and detailed directions for collecting and preserving insects according to modern methods. A bulletin on the same subject, prepared under the direction of the late Dr. C. V. Riley, was published in 1892, but since that date new methods of collecting have been devised and studies are conducted on entirely new lines, so that it has been deemed advisable to re-write the pamphlet from beginning to end. Many notes on the preparation of insects for the cabinet have been copied from various entomological journals, while special information has been supplied in regard to particular groups by members of the Bureau of Entomology. The work commences with a general review of the different orders of insects and their developmental history, after which come directions for capture and preservation in the field and mounting and storing in the museum. Figures of apparatus of all kinds are given, accompanied by full descriptions of the cabinets employed in the U.S. Museum. The scope of the work likewise includes directions for rearing live insects and maintaining them in captivity, while the collection and preservation of spiders, scorpions, and centipedes also come within its purview.

A report by Dr. Newsholme and Sir Malcolm Morris, K.C.V.O., the British delegates to the International Conference on Leprosy held at Bergen in August last, has been issued as a Parliamentary Paper (Cd. 4916). They, together with several delegates from British colonies, formulated several resolutions for the control of the disease, the chief of which are as follows:—(1) Leprosy is spread by direct and indirect contagion from persons suffering from the disease. The possibility that indirect contagion may be effected by fleas, bugs, lice, the itch parasite, &c., has to be borne in mind. (2) Leprosy is not due to the eating of any particular food, such as fish. (3) There is no evidence that leprosy is hereditary. (4) In leprosy an interval of years may elapse between infection and the first recognised appearance of disease. (5) The danger of infection from leprous persons is greater when there is discharge from mucous membranes or from ulcerated surfaces. (6) Compulsory notification of every case of leprosy should be enforced. (7) The most important administrative measure is to separate the leprous from the non-leprous by segregation in settlements or asylums. (8) In settlements home life may be permitted under regulation by the responsible authorities.

A selection of new or noteworthy Philippine plants described by Mr. Merrill, forming the seventh series, is published in the *Philippine Journal of Science* (August). The majority of the determinations refer to tree specimens, and include new species of Diospyros and Cryptocarya, also additions to the families Meliaceæ and Flacourtiaceæ. In the latter family the author finds a similarity between Philippine and Ceylonese species. A new genus, Embolanthera, allied to Maingaya, is created in the Hamamelidaceæ, and Everettiodendron in the Euphorbiaceæ. A noteworthy new species is *Chonemorpha elastica*, an asclepiad, which promises to be the best native rubber-producing vine.

With the view of making the best use of their local museums, the Essex Museum of Natural History, Stratford, and the Epping Forest Museum, Chingford, the Essex Field Club held during the previous winter two conferences to discuss the use of museums for promoting nature-study in schools, which are reported in a small pamphlet recently published. At Stratford educational facilities are provided in the form of mounted specimens, drawings, and explanatory labels, while at Chingford the exhibition of seasonal plants and branches is made a special feature. Nevertheless, it was agreed that a museum is not the place to hold nature-study classes for children, although well adapted for classes of teachers. Prof. R. Meldola, in testifying to the value of nature-study, expressed the opinion that it should be regarded as a method of training, not as a subject for teaching, and that it should include the study of the inorganic world; he also emphasised the necessity for nature-taught teachers.

The dispersal of plants was a subject to which the late Prof. Errera devoted much attention, and among the problems which came under his notice was the manner in which plants manage to reach rocks isolated by glaciers. In this connection he visited the isolated peaks, Aguagliouls, by the side of the Roseg glacier, and Isla Persa, flanked by the Morteratsch glacier. A posthumous paper published in the *Recueil de l'Institut botanique Léo Errera* (vol. viii.) contains a list of the plants collected on these rocks and on the moraine adjoining the former. There is a remarkable contrast between the species growing on the peak Aguagliouls and the moraine; on the moraine three species of Trifolium and *Anthyllis vulneraria* were taken, and Primulas were wanting, while on the peak the Leguminosæ were represented by one Trifolium, but six species of Primula were collected.

The vigorous efforts made by the American agricultural colleges to get into touch with the practical man are well exemplified by the large numbers of bulletins they issue dealing with every phase of agriculture and every problem about which it is supposed the farmer requires help. We have received a series of bulletins from the Colorado Agricultural College which are quite typical of their kind; the subjects dealt with are the cultivation of fruit trees, pig production, and the manufacture of gate-posts out of cement. The bulletins are drawn up by experts, are clearly written, and well illustrated. The cost of production and distribution must be considerable.

The United States Department of Agriculture has recently issued a popular bulletin by Mr. Milner on the use of milk as food. It is stated that about one-sixth of the total food of the average American family is furnished by milk and its products. A simple account is given of its properties and of the effects of bacteria; a number of milk products are described, and comparison is instituted between these and other nutrients. It is further shown that milk is quite as economical as other animal foods, but dearer than most vegetable products; as a source of protein it is especially economical.

WE have received from the Michigan State Agricultural College Experiment Station a bulletin describing a local cattle disease known as the Grand Traverse or Lake Shore disease. At the outset the head is carried low with drooping ears, the coat stares, and the appetite falls off. The animals drink less and less as the disease advances, until finally they refuse to drink at all. As the appetite fails it becomes depraved, and such materials as bones, wood, leather, rope, or bark are eaten. The animals become extremely emaciated. The seat of the disease appears to be in the third stomach, where extensive lesions are often found. The cause of the disease is obscure, but some evidence was obtained that showed it lay in the methods of feeding. Experiments to test this view are in progress.

AMONG some miscellaneous publications to hand from the United States Department of Agriculture is one on the method of winter fumigation for the white fly infesting citrus trees. The tree is covered with a sufficiently large tent in which hydrocyanic acid is being generated; by careful attention to certain details the fly can, it is said, be exterminated at a small cost. A Farmers' Bulletin gives a short summary of the results obtained at some of the agricultural experiment stations. No fewer than ten different subjects are dealt with, and references are given to the original sources, from which farmers who wish to do so can readily obtain fuller information. Another bulletin describes the card-index sets now being made up and sold, in which are catalogued the publications of the Departments of Agriculture, the Geological Survey, and the State Surveys. Such an index is indispensable in the United States, where an enormous number of official publications are issued every year.

THE *Geographical Journal* for November contains a short report, by Sir Ernest Shackleton, on some results of the British Antarctic Expedition of 1907–9. The paper gives a summary of the routes of the chief expeditions from the headquarters at Cape Royds, and a brief narrative of the most important events which occurred during each. It is announced that most of the volumes containing the scientific records and results of the expedition will probably be issued within the next twelve or eighteen months. The contribution is accompanied by three maps.

DR. WARREN DU PRÉ SMITH, chief of the Division of Mines, Bureau of Science, Manila, contributes a paper to the November number of the *Geographical Journal* on geographical work in the Philippines. The work under the American *régime* is carried on primarily by the United States Coast and Geodetic Survey, which is responsible for the most accurate surveys, but mapping is also done by the United States Army, the Bureau of Constabulary, the Bureau of Lands (cadastral surveys), and the Division of Mines. The land area of the Philippines is approximately 115,000 square miles, and of this about 14,000 square miles had been covered by triangulation, and the topography of 1500 square miles mapped up to June 30, 1908.

THE *Revue des Idées* for October contains an article, by Prof. Jacques Loeb, of California, entitled "Les Tropismes et la Psychologie." The writer refuses to accept the common view that a physical interpretation, however complete, of a psychical phenomenon can never afford an explanation of its psychical character. He maintains that the "will" of an animal is merely a term useful to cloak our ignorance of the forces determining its movements, and that the scientific solution of the problem of volition consists solely in discovering those forces and the laws according to which they act. He adduces evidence in favour of attributing to positive or negative heliotropism the reactions of aphides, bees, ants, &c., to light. He combats the experimental work of Jennings and others who claim to have established the inadequacy of mechanical processes to account for the behaviour of even the lowest organisms.

MR. G. L. GOMME contributes to the *Sociological Review* for October an important paper treating of sociology as the basis of inquiry into primitive culture. He lays down as the fundamental proposition of anthropological research "that inquiry into the culture and condition of primitive man as he is represented by modern savages, in the remains of decayed civilisations, or in the ancient records of the beginnings of modern civilisations, can only be conducted by considering each item of culture which is the subject of inquiry in association with all the other items of culture in the same social group." The original social unit consists of the tribal rulers and the tribal village, representing the one a conquering, the other a conquered, race. Slavery in Indo-European society means, not personal servitude, but the status of a class springing from the conquered people. Indo-European tribalism is not only a polity, but a religion, and it was indestructible. The tribe is founded, not alone on blood kinship, but also on common worship. He perhaps goes too far in extending Robertson Smith's theory of sacramental kinship with the deity to non-Semitic communities; but, with this reservation, his study of early tribal origins is interesting and suggestive.

PEOPLE who are seriously interested in aërial navigation will regret that the weekly *Ila*, issued in connection with the Frankfurt Exhibition, terminated on October 16. The seventeen issues contain many important and well-written articles dealing with various aspects of aërotechnics. Among the subjects treated are aërial motors, by E. Rumpler; materials and machinery, by August Bauschlicher; measurements of air resistance at Lindenberg, by Dr. F. Bendemann; aërial electricity, by O. Voigt; wind statistics, by W. Peppler; bird flight, by F. W. Lanchester (translated by H. Hochschild); the special steel industry, by W. Eilender; meteorological statistics for airships, by W. Peppler; balloon photography, by Captain Scheimpflug (abstract); aërodynamical researches, by Prof. Ahlborn (some of whose photographs of stream lines closely resemble those recently obtained by W. E. Williams in this country); besides unsigned articles on vehicles for transport of hydrogen, lamps for hangars, the Parseval balloon, and technical notes. The seventeen numbers of *Ila* will preserve their place in the literature of aërotechnics long after the great majority of journals of mushroom growth have passed into oblivion.

SEVENTY out of the hundred and eighty pages of the August number of the Proceedings of the American Philosophical Society of Philadelphia are devoted to papers dealing with seismological subjects, some of which have been mentioned already (June 10, vol. lxxx., p. 444). The first, on the causes and effects of earthquakes, by Mr. E. O. Hovey, treats the subject in a popular manner, and contains descriptions of the Charleston (1886), the California (1906), the Kingston (1907), and the Messina (1908) earthquakes. The second, by Mr. W. H. Hobbs, deals with the evolution and outlook of seismic geology, and advocates two lines of advance:—first, to make practical use of the knowledge already gained, and second, to refine our instruments until we are capable of forecasting the time, place, and severity of the next earthquake. He points out the importance, as a means of forecasting, of the principle of immunity from shock for a long period of a region which has just experienced one, and suggests that more refined instruments may show that slight tremors precede all shocks. A third paper, by Mr. H. F. Reid, urges the United States Government to found a seismological bureau for the study of earthquakes, particularly in the United States.

Marine steam turbines show generally a lower efficiency as compared with corresponding land turbines on account of the compromise which has to be made regarding speeds of revolution. This is owing to the fact that the propeller has best efficiency at comparatively low speeds, while the turbine gives best results at high speeds. In *Engineering* for November 5 is described one of the several methods which have been tried for securing a reduction of speed from the turbine to the propeller, thus enabling both to be worked at their best speeds. The arrangement is due to Dr. Föttinger, of the Vulcan Company, of Stettin, and consists of a differential water-turbine transmitter in which the primary water-wheel is driven by the steam-turbine shaft, and transmits water with a certain velocity through guide blades or directly to a secondary wheel or wheels mounted on the secondary or propeller shaft in the same axial plane. Transmission ratios of from 3/1 up to 12/1 can be provided, and reversal can be obtained by means of a reversing water-turbine transmitter of somewhat similar design on the same shafts. With an experimental installation at the works in which the primary shaft runs at 1600 revolutions per minute and the propeller shaft at about 270 ahead, reversal to 250 revolutions astern can be obtained in nineteen seconds. The efficiency of power transmission rises rapidly to 78 per cent. at 600 revolutions per minute of the primary shaft, and remains constant at 83 per cent. at 1250 revolutions. This installation has a transmission ratio of 4·5 to 1. The Vulcan Company have built a special steamer for trials with this arrangement, and it will also be probably tried on warships. The arrangement seems to be valuable and likely to come into extensive use.

We have received from Mr. Bernard Quaritch, 11 Grafton Street, New Bond Street, London, a copy of his current issue of rare and valuable books now offered for sale. The list includes many interesting volumes concerned with America and Australasia.

Messrs. Longmans, Green and Co. will publish in a few days "Beasts and Men: being Carl Hagenbeck's Experiences for Half a Century among Wild Animals," an abridged translation by H. S. R. Elliot and A. G. Thacker, with an introduction by Dr. P. Chalmers Mitchell. Carl Hagenbeck is the founder of the famous Zoological Park at Stellingen, near Hamburg.

Reference has been made before in these columns to the convenience of the circulating library of Mr. H. K. Lewis, Gower Street, London, to students of science and others. The most recent list of new books and new editions added to the library during July, August, and September of the present year shows that great pains are being taken to keep the library complete and up to date.

The Cambridge University Press announces as in the press "Mathematical and Physical Papers," by the late Lord Kelvin, vol. iv., hydrodynamics, containing vortex motion, tides, and waves on water, collected and arranged by Sir J. Larmor, secretary of the Royal Society. The same publishers have in preparation "Lord Kelvin: Scientific Remains," including excerpts from early diaries and from his scientific correspondence, together with a reprint of the historical account of his scientific career prepared for the obituary notices of the Royal Society. This work is also by Sir J. Larmor.

OUR ASTRONOMICAL COLUMN.

A Brilliant Meteor.—A magnificent meteor was observed, at 11h. 59m., at the Solar Physics Observatory, South Kensington, on November 15. The observed path was from about $114\tfrac{1}{2}^\circ$, $+27\tfrac{1}{2}^\circ$ to $87\tfrac{1}{2}^\circ$, $+6^\circ$, *i.e.* from immediately below Pollux to immediately below Betelgeuse, the path being nearly horizontal.

The meteor was very bright, exhibited striking red and greenish tints, and travelled with a medium velocity. It did not explode, but the large bright head simply faded away, leaving a definite trail, which endured for some two or three seconds.

Elements of Halley's Comet.—The following five elements of Halley's comet are those calculated by Mr. P. H. Cowell, F.R.S., and Mr. A. C. D. Crommelin, from the perturbations since 1835:—

Longitude of ascending node	57 16 12
Node to perihelion	111 42 16
Inclination of orbit	162 12 42
Semi-major axis of ellipse	17·94527
Eccentricity...	0·967281

The above elements have not yet been re-determined from recent observations.

The predicted date of perihelion passage was 1910 April 16·6.

The observed positions in 1909 September and October can be satisfied, both in right ascension and declination, by altering the date of perihelion passage to 1910 April 19·7 and retaining the predicted values of the other elements.

Recent Observations of Mars.—In No. 4367 of the *Astronomische Nachrichten* M. Jonckheere gives 24·325″ as the mean diameter of Mars from several observations near opposition; at unit distance this would be 9·533″, which means that if the diameter of the earth be taken as 1·0, that of Mars is 0·540. The observed flattening of the polar diameter was 1 : 270·8. A list of nine probably new canals is given, names being proposed for six of them which are certainly novel.

In No. 4368 of the same journal M. Jonckheere gives two drawings, made on September 30, 11h. 30m. (long. 210°), and October 5, 10h. 10m. (long. 145°), respectively. On the former date a number of "lands" and thirty-four canals, four probably new, were seen, and on the latter date forty-nine canals, six probably new, and seven "lands" were recorded. Among the latter were the two new ones, Stella, near the polar cap, and Thaumas, in the Aonius Sinus.

No. 4367 also contains a note, by M. Jarry Desloges, recording the observation and disappearance of a terminator projection in the region of Daedalia, variations in the Lacus Solis, the Auroræ Sinus and Deucalionis Regio, and the discovery of two new canals.

A paper by M. Desloges also appears in No. 17 of the *Comptes rendus* (October 26), in which the author divides the canaliform markings into three types:—(1) broad greyish bands; (2) lines of medium breadth, very dark, and with definite edges; (3) fine lines near the limit of visibility. He suspects that some features of the first type have, at times, been resolved into finer details, whilst among those of the second type changes have undoubtedly taken place. The finer markings, type 3, appear to have become greatly augmented in number. His collaborators, MM. Fournier, saw Araxes, type 1, single, then double, and finally triple, but M. Desloges himself has never been certain of seeing a canal doubled. Two charts given in the paper show the Martian features in spring (southern hemisphere), and later at the beginning of summer, and it is seen that at the later epoch the markings were more numerous and better defined.

Perrine's Comet, 1909*b*.—From the recent observations (August–October) of Perrine's periodical comet Dr. Kobold has calculated a set of elements, which he gives in No. 4368 of the *Astronomische Nachrichten* (p. 405, November 10); this gives the perihelion passage as 1909 October 31·865 (M.T. Berlin). An ephemeris is also published showing that the comet is apparently travelling, nearly due south, through Gemini, as shown by the following positions:—November 18, 7h. 3·8m., +17° 46·8′; November 30, 7h. 11·9m., +5° 45·5′. On November 19 the comet will be some minutes west of λ Geminorum, and of about magnitude 12·3.

The Liverpool Astronomical Society.—The annual report of the Liverpool Astronomical Society shows that its activity and membership are being well maintained. In the presidential address Mr. W. E. Plummer gives an interesting paper on satellites, and other notes, by Mr. Thorp and Father Cortie respectively, deal with diffraction gratings and sun-spot spectra. There is also a paper on Morehouse's comet, illustrated by a frontispiece reproducing photographs taken by four of the society's members.

The Parallax of the Double Star Σ 2398.—In these columns on September 16 we directed attention to Dr. Bohlin's re-determination of the parallax of the double star Σ, from which it followed that this star, with a parallax of 0·484″, is the nearest to us in the northern hemisphere.

Since Dr. Bohlin's publication several observers have directed attention to the discordance of the above value from several previously determined, Prof. Schlesinger pointing out (*Astronomische Nachrichten*, No. 4365, p. 359) that it is probably 0·15″ too high.

Dr. Bohlin now states (*ibid.*) that an error crept into his calculations, and that, on correcting this, the parallax derived from his observations is +0·251″; there are, at least, eight or nine stars in the northern hemisphere for which greater parallaxes than this have been found.

THE MEASUREMENT OF SOLAR RADIATION.[1]

In the long memoir referred to below Dr. Bemporad discusses a variety of problems relating to the measurement of solar radiation, a subject to which he has made previous contributions. The material employed consists mainly of observations made with pyrheliometers of the now common Ångström pattern at the peak of Teneriffe during five days in June and July, 1896. Prof. Ångström and an assistant observed at two different heights, the two stations simultaneously occupied being one at a level of 3252 metres, the other at one or other of the three levels 3683, 2125, and 360 metres.

On an average day there were about sixteen observations at each of the two stations occupied. The observations were scattered over the day, the zenith distances of the sun usually ranging from a little more than 5° to between 80° and 90°. The pyrheliometer reading on reduction gives q, the heat received in unit time by a unit of surface placed orthogonally to the sun's rays. As the sun's zenith distance alters, there is at any station a change in the length of the path of the sun's rays through the atmosphere. The longer the path, the greater the loss by absorption, and the first problem considered by Bemporad is which of several formulæ, due to Crova, Bartoli, Pouillet, and himself, best represents the variation of q with zenith distance. The formulæ all contain a quantity e defined as the "mass" of air traversed by the rays (for this purpose a ray may be regarded as a tube of unit section), unity representing the value of e for a vertical ray. The author refers to a previous memoir, in which he has tabulated e as a function of z, the zenith distance, at sea-level. Treating the morning and afternoon observations of each day at each station separately, he calculates the best values for the constants q_0 and m in a formula of Crova's type $q=q_0(1+e)^{-m}$. The average difference between the individual observed and calculated values is usually well under 1 per cent. The author seems, however, to prefer a three-constant formula of the type $\log q=a-be^n$, and makes numerous comparisons with formulæ of this type.

If we neglect the earth's curvature and the small variation in z at different levels due to refraction, and regard the atmosphere as formed of "layers" bounded by parallel planes, an increase of z increases the length of path in all layers in the same proportion. Thus the formulæ involving e do not really assume that the absorption in travelling through a given "mass" of air is the same at all levels. With the view of ascertaining the variation in absorption with height, the author proceeds to calculate the "mass" of air traversed by rays, having different values of z, in passing from the level of one of Ångström's stations to another. This is got by a slight modification of the difference between the air "masses" from sea-level up to each of the two heights, as given in a table previously published by the author. One assumption in the process which rather invites criticism—though there is no obvious means of avoiding it in the absence of direct observations—is that the temperature gradient was the same at all levels and deducible from the observations at the two stations. Having found M, the "mass" of air traversed between the levels of the two stations, the author assumes that the simultaneous values q and q' of q at the two stations are connected by a formula of the type $\log(q'/q)=c\mathrm{M}$, where c is the mean absorption per unit mass of air for the layer between the two heights. Ångström's four stations supply, of course, three layers, though the data for the three refer really to different days. Thus three values of c—answering to three different layers or to three different mean heights in the atmosphere—are obtained for a series of different values of z. One noteworthy feature is the tendency of c, for a given value of z, to be greater in the afternoon than in the forenoon. The author finds c to diminish notably with the altitude of the layer, and he concludes in favour of the empirical law that the absorption at different heights varies as the fourth power of the density of the air. This conclusion was derived primarily from Ångström's observations alone, but the author tests it by reference to results obtained by Millochau at Mont Blanc, Langley at Mount Whitney, and Rizzo at Rocciamelone. On p. 97 he considers the relationship of his formula to the law of variation with height usually proposed for aqueous vapour.

In an earlier paper the author had tabulated the value M of the "mass" of air traversed by a ray between sea-level and heights varying up to 5000 metres for different values of z. His calculations assumed the temperature gradient β to be 6·2° C. per km. In an appendix to the present memoir he gives the corrections to be applied to the previous table when the value of β is not 6·2°, but 6°, 5° . . . 0°. By a curious oversight the table for $\beta=2°$ is printed twice over on p. 103, that for $\beta=1°$ being omitted.

The author refers in various places to the fact that the absorption by the atmosphere is selective, the presence of aqueous vapour in the lower strata being specially important; but Ångström's observations in 1896 dealt only with the total radiation. He also recognises that the presence of a mountain may disturb the atmospheric conditions in its immediate neighbourhood. He apparently ascribes to this—and with good reason—certain anomalous results derived from Ångström's two highest stations, according to which the absorption in the intervening layer was at times negative. One cannot but entertain some doubt whether the subject is yet quite ripe for mathematical calculations of so elaborate a type as the author's. There would certainly have been a much more suitable field for their application if he had had at his disposal absolutely synchronous data from seven or eight stations—preferably in the free atmosphere—at heights differing by regular intervals of, say, 500 metres, results being obtained, not merely for the total radiation, but for the portions passed by a series of filters after the method recently proposed by Ångström.

C. Chree.

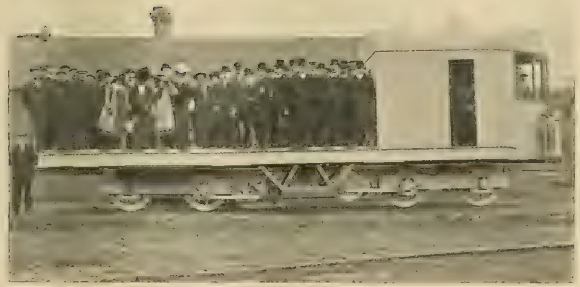
[1] "L'Assorbimento selettivo della Radiazione solare nell' Atmosfera terrestre e la sua variazione coll' altezza." By Dr. A. Bemporad. Pp. 111. From Reale Accademia dei Lincei, anno cccv., 1908. (Roma: Tipografia della R. Accademia dei Lincei, 1908.)

THE BRENNAN MONO-RAIL SYSTEM.

IT will be remembered that Mr. Louis Brennan exhibited a model mono-rail vehicle at the Royal Society soirée in May, 1907. Aided by grants from the War Office, the India Office, and the Cashmir Government, Mr. Brennan has developed the system, and we have now to record public trials of a full-sized vehicle which were made at the Brennan Torpedo Works, near Chatham, on Wednesday, November 10. A full account of the gyroscopic principles involved was given in NATURE of March 12, 1908.

The track consists of a single-rail circular portion of 105 feet radius, a straight portion 440 yards in length, and sidings. The rails are of the Vignoles section, $5\frac{3}{4}$ inches high, 70 lb. to the yard, and have the heads rounded to a radius of 5 inches. These are laid on sleepers 3 feet 6 inches long at about 3-foot centres on soft made ground, the rails being spiked to the sleepers. The points consist of two short lengths of rails fixed together and capable of sliding sideways so as to bring whichever is required into line with the fixed rails. The car is a platform 40 feet in length and 10 feet in width, having the machinery cab at one end, and is supported on two bogies, the centres of which are 20 feet apart. Each bogie has two double-flanged wheels 3 feet in diameter, of wheel base 5 feet 4 inches. To obtain flexibility in rounding curves, the bogies have their centre pins connected to the body by means of ball bearings. The empty car weighs 22 tons, and is designed to carry a load of from 10 to 15 tons.



Four-wheel self-propelling mono-rail car.

The power required is derived from two petrol-electric sets of 80 and 20 horse-power respectively, the petrol engines being direct-coupled to dynamos. It is, of course, possible to collect current from an overhead wire, or to use steam or other motive power. Current is supplied from the generating sets to two 40 to 50 horse-power motors on the bogies for propulsion, the motors being geared to an intermediate shaft, from which the wheels are driven by balanced cranks and coupling rods. Current is also supplied to the gyroscopic motors, to a compressor for operating the Westinghouse brake and the gyroscopic control gear, and to a small motor driving an oil pump.

Each of the two gyroscopic wheels is 3 feet 6 inches in diameter, and weighs three-quarters of a ton; the axes are normally horizontal, and perpendicular to the direction of the rail. Each is driven at 3000 revolutions per minute by a direct-current shunt motor, having the field magnets on the frame and the armature on the gyrostat shaft. The whole is cased in, and a vacuum is maintained of $\frac{1}{2}$-inch to $\frac{5}{8}$-inch of mercury for the purpose of minimising the air resistance. Although the vacuum will last several hours, a pump is kept running in order to keep it as low as possible. Mr. Brennan has noticed that, while the motors run cool under a good vacuum, they become hot directly air is admitted to the casing. The shafts have steel journals running in white-metal bearings under forced lubrication, the oil being cooled before being returned to the bearings.

During the trials on November 10 the smaller generating set alone was in operation, giving a speed of seven miles per hour. At this speed there was no difficulty in carrying forty persons round the circular track, on to the straight, and over reverse curves of 35 feet radius without material disturbance of the level of the car floor. Loaded on one side, the car-level first rises on that side and then gradually recovers; the steadiness is admirably shown by one of the photographs taken, showing thirty-six persons standing as close as possible to one edge of the platform with the car at rest. Mr. Brennan states that a load of two tons can be placed on the edge of the platform and then removed without danger of non-recovery of the level. The car at present can negotiate grades of 1 in 13, and, with an additional generating set, grades of 1 in $6\frac{1}{2}$ could be surmounted. Finality in design cannot be said to be reached as yet, and Mr. Brennan thinks that development will proceed in the direction of high-speed passenger trains having speeds up to 150 miles per hour.

THE RISE OF SCIENTIFIC STUDY IN SCOTLAND.[1]

AS the Royal Society is now about to open a fresh page in its history, it may not be regarded as an inopportune moment to sketch the rise of scientific study in Scotland, the means and opportunities afforded for that purpose, the formation of societies and institutions for the encouragement and diffusion of science in Edinburgh; also to put in the form of a continuous narrative the chief incidents in the growth of the society during the century and a quarter that has elapsed since its foundation.

Prior to the eighteenth century, and indeed during a considerable part of its course, Latin was the language in use for the interchange of thought and information amongst educated people at home and abroad. Treatises were composed in this language, lectures were delivered in the universities in Latin, and the theses presented for graduation were written and defended in the same tongue. Readiness to speak and understand Latin was a common bond of union amongst the learned, and distinguished them from the unlettered classes, whether of higher or lower social degree. Scotland participated in the revival of letters during the sixteenth century, and the names of George Buchanan, the representative Scottish humanist and historian of his time, of Andrew Melville, humanist and theologian, of James Crichton, surnamed the Admirable, were familiar to scholars throughout Europe. Contemporaneous with Andrew Melville was John Napier, the laird of Merchiston, the inventor of logarithms, a man of a different order of mind from the famous divine, one who by the publication of his great treatises, which were written in Latin, created a fresh era in the science of numbers, and provided mathematicians with a new and powerful instrument. To be conversant with Latin was a necessity for all who aspired to take rank in their respective professions. Those whose means enabled them to travel and to study in foreign universities could avail themselves of the instruction imparted therein, without requiring to have, as a preliminary, a good acquaintance with the language of the people. To cite an illustrious example from the south of the Tweed. William Harvey, the son of a Kentish yeoman, was educated in classics and physics at Gonville-Caius College, Cambridge. In 1598 he went to the University of Padua, where he studied under Fabricius, at that time the most eminent professor of anatomy in Italy. Profiting by the best means of instruction available at that time, and as a result of his own subsequent and independent observations and experiments, he discovered the circulation of the blood, and wrote his treatise "De motu Cordis et Sanguinis," which has made his name immortal, and has entitled him to be called the founder of exact physiological science, and the father of modern medicine.

---

[1] Abridged from an address delivered before the Royal Society of Edinburgh on the occasion of the opening of the new home of the society, November 8, by Sir William Turner, K.C.B., F.R.S., president of the society.

Ambitious young Scotsmen did not lag behind in the desire to extend and perfect their studies by residence at schools of learning on the Continent. Literature, philosophy, and theology at first were the subjects of attraction; but later on medicine and science were cultivated with great zeal, and instruction and training in their application were obtained abroad of a quality surpassing that procurable in the universities of their native land.

In the latter half of the seventeenth century, three Edinburgh physicians, Sir Robert Sibbald, Sir Andrew Balfour, and Dr. Archibald Pitcairne, all of whom had studied abroad, took a leading part in the development and cultivation of medicine and science in Edinburgh.

Sibbald, Balfour, and Patrick Murray, the laird of Livingstone, being desirous of encouraging the study of botany, were bent on founding a medicine or physic garden, and, acting in conjunction with some other physicians, obtained a lease from the Town Council of the garden of Trinity Hospital for that purpose. They imported plants and seeds from abroad, obtained subscriptions from the nobility, the Exchequer, and members of the College of Justice, and established the garden which was the precursor of our world-famed Royal Botanic Garden.

In 1680 Drs. Balfour, Archibald Pitcairne, Sir Thomas Burnett, and other physicians met once a fortnight or so in Sibbald's house, to confer on "what was most remarkable a doing by the learned, some rare cases that had happened in our practice, and ane account of Bookes that tended to the improvement of medicine or natural history, or any other curious learning." So far as I have been able to ascertain, these conferences marked the first attempt in Scotland to bring together at regular intervals, for purposes of discussion and mutual improvement, those who had common interests in science and medicine. On St. Andrew's Day, 1681, after much negotiation, conducted principally by Drs. Sibbald, Balfour, and Stevenson, and with the aid of H.R.H. James, Duke of York, and Sir Charles Scarborough, His Majesty's first physician, a patent was granted by King Charles II. to found the Royal College of Physicians of Edinburgh, and in 1684 Sibbald was elected president of the college. After its institution the meetings for discussion and interchange of ideas were discontinued in Sibbald's hause, and were held monthly in the college.

In granting a charter in July, 1662, to the Royal Society of London, and one in 1681 to the Royal College of Physicians of Edinburgh, Charles did two wise actions, which have encouraged science, medicine, and learning, and therein have redounded to his honour and to that of his kingdom.

The scientific spirit and foresight shown by Balfour and Sibbald more than two centuries ago gave an impetus to the study of the natural sciences in Scotland, which as time went on resulted in the establishment of two institutions of which Edinburgh may well be proud, the Royal Botanic Garden and the Royal Scottish Museum.

Early in the eighteenth century, and during its continuance, a remarkable intellectual awakening took place in Scotland. Public affairs, with the exception of the abortive Jacobite risings in 1715 and 1745, had by this time become more settled. Through the development of agriculture, mining, manufactures, and commerce, Scotland had begun to emerge from being a poor country to a state of comparative affluence. Men found it possible to direct their thoughts to the arts of peace and to study letters, philosophy, and science. Within the universities, as well as in cultured society outside them, men of marked ability came prominently to the front, many of whom acquired, and have retained, a world-wide reputation.

An important change took place within the universities themselves in connection with the methods of instruction imparted in the faculty of arts. The old system of regents, under which it was the duty of each regent to act as tutor to a group of pupils from entrance to laureation, in all the subjects of a prescribed curriculum, began to be abolished, and a special subject was allotted to a particular teacher, who became a professor in that subject.[1] Encouragement was in this way given to a more profound study and fuller exposition of the subjects entrusted to the professors. Mathematics and philosophy, both natural and mental, especially commended themselves to the Scottish intellect. Great developments also took place in medicine and in the sciences on which it is based. The incorporation of the physicians of Edinburgh into a Royal College in 1681, the severance in 1722 of the corporate interests of the surgeons from those of the barbers, and the granting a new charter in 1778 to the surgeons, which incorporated them as a Royal College, greatly improved the tone and status of the medical profession in Edinburgh and in the adjoining counties.

As an indication of the value attached in Scotland during the eighteenth century to the medical education to be obtained in foreign universities, I may state that, from the foundation of the medical faculty in Edinburgh in 1726 until about the end of the century, fourteen of the professors in that faculty studied, either in whole or in part, in universities in Holland, France, or Italy, and many took the degree of Doctor of Medicine abroad. Of these, ten were educated at the University of Leyden, to which they had been attracted by the fame of Boerhaave.

The language common to all cultured people at that time enabled students to migrate from one European university to another, and to converse and receive instruction through one of the noblest of tongues, without having to resort to such mongrel forms of speech, to facilitate general intercourse amongst the nations, as have recently been devised by some ingenious persons. In the quality and range of their education and intellectual attainments, professors of science and the leaders in medicine were on an equal footing with the members of the Church and Bar, and with those who cultivated philosophy and literature. Members of the several professions acquired the habit of meeting together on a friendly footing, and were often joined by country gentlemen living in proximity to Edinburgh. Clubs and societies of various kinds, literary, social, medical, scientific, and legal, became the fashion.

In 1731 the leading physicians and surgeons in Edinburgh instituted a Medical Society for the improvement of medical knowledge. Monro *primus* acted as secretary, and under his supervision six volumes of "Medical Essays and Observations" communicated to the society were published. The "Essays" reached a fifth edition in 1771. They were translated into some foreign languages, were highly commended, and assisted in making the medical school of the University known throughout Europe. Shortly after the formation of the Medical Society several of the leading lawyers, professors in Edinburgh, Glasgow, and St. Andrews, country gentlemen, William Adams the architect, and others, formed a Society for Improving Arts and Science, particularly Natural Knowledge. Colin Maclaurin was the moving spirit; he and Andrew Plummer were secretaries, and the first president was James Douglas, fourteenth Earl of Morton, who became in 1764 president of the Royal Society of London.

(It may not be out of place to refer to the part taken by Scotsmen in the early history of the Royal Society of London. In the original charter appear the names of Sir

---

[1] During the incumbency of the regents, Latin was the medium of intercourse between teachers and students. After the introduction of professorships the lectures in many subjects were delivered in Latin well into the eighteenth century. Sir Alexander Grant says that St. Clair, professor of medicine, lectured in Latin (1726–1747), as indeed was the practice with all the faculty of medicine, except anatomy. In Glasgow, Cullen lectured (1748) on botany in Latin, but his lectures on medicine were delivered in English. Sir Robert Christison relates in his "Autobiography" that in 1810 his oral examination for the degree of Doctor of Medicine was conducted in Latin. The theses presented for graduation in medicine in Edinburgh were written and printed in Latin down to 1833, and an occasional thesis in the same language was presented as late as 1844.

Robert Moray, Secretary to the Privy Council in Scotland, and William Aerskine (Erskine), a son of the Earl of Mar, one of the cupbearers to King Charles. They had been his companions in exile, and after the Restoration they were attached to his court and person. Moray had scientific tastes and pursuits, which led to his election as president of a society for the promotion of physico-mathematical experimental learning, which met in Gresham College, London, 1661–2. This society became, on the receipt of a Royal charter in July, 1662, the Royal Society of London, under the presidency of William, Viscount Brouncker. Moray had without doubt been the King's adviser in the granting of the charter. About a century later James Douglas, Earl of Morton, a mathematician and astronomer, a friend of Colin Maclaurin, and a former president of the Philosophical Society of Edinburgh, was in 1764 elected president of the Royal Society of London. Eight years later Sir John Pringle, of the family of Stichel, was made president. He had graduated as M.D. at Leyden in 1730, and settled in Edinburgh, where he held the chair of moral philosophy in the University from 1734 to 1742. He then joined the army as a surgeon, ultimately became Physician-General to His Majesty's forces, wrote a famous book on "Diseases of the Army," resided in London, and in 1772 was appointed president. After a long interval Lord Kelvin occupied the chair, 1890–5, and last year Sir Archibald Geikie was made president. Although not of Scottish birth or parentage, Scotland may claim to have participated in the training of Sir J. Dalton Hooker, president 1873–8, who was educated at the High School and University of Glasgow during his father's tenure of the regius chair of botany in the University; also of Lord Lister, president 1895–1900, who carried out his far-reaching researches when he held the chair of systematic surgery in the University of Glasgow, and subsequently that of clinical surgery in the University of Edinburgh.)

It does not appear that any of the communications made to the society in its early years were immediately published, as the troubles which arose in connection with the Jacobite rising in 1745, and the death of Maclaurin in the following year, suspended for a time its work. Proposals had been, however, made to the Medical Society to form along with it a conjoined society, which should carry its disquisitions into other parts of nature than those which immediately related to medicine, on the understanding that theology, morals, and politics were to be excluded. The larger society formed by this combination became the Philosophical Society of Edinburgh, and it published between 1754 and 1771 three volumes of "Essays and Observations, Physical and Literary," which had been read before the society, the last two of which appeared when David Hume and Monro *secundus* were secretaries. The "Essays" embraced a wide range of subjects, mathematical, physical, anatomical, botanical, medical, and surgical. Vol. i. is of interest in containing two papers by Alex. Monro, jun., afterwards *secundus*, then a student of medicine; and in vol. iii. a letter to David Hume is printed, dated 1762, in which Benjamin Franklin described his method of securing houses from the effects of lightning. To quote the words of Principal Forbes, the Philosophical Society of Edinburgh was the immediate parent of the Royal Society. As the Philosophical Society was a voluntary association, liable to be interrupted in its work, or even to be dissolved, it was considered advisable that an attempt should be made to form a society on a more permanent basis. A meeting of the professors of the University, many of whom were likewise members of the Philosophical Society, was called in 1782, when Principal Robertson proposed a scheme "for the establishment of a new society on a more extended plan, and after the model of some of the foreign academies, which have for their object the cultivation of every branch of science, erudition, and taste." As in the formation of the Royal Society of London, the patronage of the King had been solicited, and a charter of incorporation by the Crown obtained; a similar course in this instance was proposed and agreed to, and in March, 1783, King George III. granted a charter under the name of the Royal Society of Edinburgh.

The charter provided "ut Societas Literaria Edinburgi instituerctur, ad Statum illius partis Imperii nostri quæ Scotia vocatur accommodata," from which it is obvious that its scope was not limited to the city after which it was named, and in which it had its seat, any more than the corresponding Royal Society in the southern division of the kingdom was exclusively a society for London itself. The charter defined the range of study and research to be included in the work of the society, and specifically named along with the sciences of mathematics, physics, chemistry, and natural history, also archæology, philology, and literature.

The first meeting of the society was held on June 23, 1783, in the University library, with Principal Robertson in the chair, when it was resolved that all the members of the Philosophical Society should be assumed as members of the Royal Society, and that the judges of the Supreme Court and a number of other gentlemen should be invited to join it. The society in its first year had as president Henry, third Duke of Buccleuch, and numbered 102 resident and 71 non-resident members. It is interesting to note that the Senatus of the University of St. Andrews was represented by ten members, King's and Marischal's Colleges, Aberdeen, by sixteen, whilst fifteen members of the Senatus of the University of Glasgow were original fellows, so that its national character was emphasised from its foundation.

The fellows were divided into two classes, physical and literary, and a short time after the foundation of the society the physical class numbered 101, whilst the literary class contained 114 fellows. In the first four volumes of the Transactions of the Royal Society, from 1783 to 1797, the papers were grouped into two classes. In vol. i. twelve physical papers were published and eight literary; in vol. iv. thirteen physical papers and only two literary. It became obvious, therefore, at an early date that the physical or scientific work of the society would dominate the literary. In vol. v. (1805) it was not thought necessary to divide the published memoirs into these groups, and two papers on literary subjects and two biographies were printed without being classified apart from those relating to science. In the course of time communications on literary subjects became so few in number that they formed only a small part of the work of the society.

The society commenced to publish its Transactions in 1788, and up to the present date forty-six quarto volumes have appeared. Vols. i. to v. contained chapters entitled "History of the Society," which included its Proceedings from 1783 to 1805. The publication of the Proceedings was then suspended for nearly thirty years, but in December, 1832, the society began to issue the Proceedings independently, from which date to May, 1844, they were collected, and published in 1845 in an octavo volume, to be followed by twenty-five similar volumes up to 1907, when they were enlarged to a super-royal octavo.

The scheme for the encouragement of research, recently inaugurated by the Carnegie trustees, by the institution of fellowships and scholarships, has made a provision to aid in the maintenance of men of science of the younger generation during their years of probation. The conferring of grants of money to meet the expenses of research and publication has rendered valuable assistance to scientific and other investigators, and has enabled our society to provide more complete and finished illustrations to some of the memoirs than would otherwise have been possible.

Those of us who commenced scientific work fifty or more years ago cannot but recognise the enormous advance which has been effected in recent years in providing means and facilities for exact inquiry. Natural objects were present and visible to us and to our predecessors then as now. But the present methods of study are more exact, and opportunities for its pursuit are more easily obtained; instruments of research have become more powerful and more capable of assisting in penetrating deeper into the secrets of nature; novel phenomena have been disclosed to view and call for interpretation by men of science. The field of research is far from being barren and exhausted, for it is, and will continue to be, capable of producing ever-ripening fruit. It will be for the younger fellows and for those who may succeed them to bear their share in the extension of natural knowledge, to undertake the responsibility of continuing the work of the society, and to preserve the place which it has gained in the forefront of kindred institutions.

EXPERIMENTS AT HIGH TEMPERATURES AND PRESSURES.[1]

WITHIN a few miles of this lecture-room there is an unexplored region—to approach it we should have to move vertically downwards. It has been suggested by Mr. Parsons[2] that it would be worth while to make a short expedition in this direction, but the journey would be slow and the cost high—for instance, to bore a hole twelve miles deep was estimated to be a labour which would occupy eighty-five years and cost 5,000,000*l.* A well-to-do man desiring to benefit his fellow creatures could not do better than undertake this project, but until he comes forward we must perforce be content to try to imitate in our laboratories the temperature and pressure conditions which would be met with deep down in the earth.

Information, attainable from experiments under these conditions, is essential to the development of any exact concept of the structure and evolution of the earth. One of the most important questions in connection with the study of bodies under high pressures and at various temperatures is as to whether any particular body is solid or liquid under specified conditions, and, if solid, whether it is amorphous, glassy, or crystalline. That pressure would influence the melting point of solids was clearly put forward by Clapeyron in 1834, but it was not until after the establishment of the mechanical theory of heat in the "forties" of the last century that the exact numerical relations could be established, as was done by Prof. James Thomson in 1851, when he calculated, for the first time, the amount by which the temperature of fusion of ice would be reduced by a given increase of pressure. The ideas underlying such calculations are based on a consideration of the way in which heat is converted into mechanical work in any prime mover depending on a heat-supply, and were first formulated by Carnot in 1824, before the true nature of heat was understood. As the matter is fully dealt with in every text-book, I will merely remind you that Prof. James Thomson was able to obtain an equation between the mechanical work actually produced under stated conditions and the work which, according to Carnot's principle, must be developed by a reversible engine operating between fixed temperature limits upon a given amount of heat.

The general relation for a substance undergoing a change of state at absolute temperature T, such change involving a change of volume Δv and an absorption or emission of heat at constant pressure Q_p, is, reserving the question of sign,

$$\frac{dT}{dp} = \frac{\Delta v T}{Q_p}$$

or, in words, the change of melting point produced by unit change of pressure equals the product of the absolute temperature, and the ratio of the change of volume of unit mass on melting to the quantity of heat absorbed or emitted by unit mass in the process.

Now the greater number of substances when they pass from the liquid to the solid state evolve heat and contract in volume. An increase of volume is, of course, a positive quantity, and if heat is absorbed during this increase it is reckoned positive also. In the case of water, heat is evolved during freezing as in other cases, but the mixture of ice and water has a smaller volume than the solid ice. Accordingly, the change of volume in this case is negative, and the melting point falls as the pressure rises.

The first fairly exact confirmation of the theory appears to be due to De Visser;[3] who selected acetic acid most carefully purified as a test substance, though valuable experiments up to much higher pressures had been previously made by many others, particularly by Dewar on water,[4] Ferche on benzol,[5] and Damien[6] on a variety of substances.

It is necessary to work with a pure substance in order to test the theory, or at all events with one the solid phase of which has the same constitution as its liquid phase. If the acetic acid had not been pure, the probability is that the frozen part would have contained more or less of the impurity than the unfrozen, and consequently a state of affairs not contemplated in the theory would have arisen. From the experimental point of view, it is obvious that a sharp melting point is a necessary condition for its accurate observation.

A quantity of acetic acid—rather more than 40 c.c.—is confined by mercury in a closed apparatus based on a previous design by Bunsen, which also contains air in a graduated tube. When the acetic acid melts it expands, and compresses the air through the intermediary of the mercury, whereby the pressure can be inferred. The part of the apparatus containing the acetic acid is immersed in a bath which can be kept at any desired temperature. As the melting progresses a pressure is set up by the expansion, and finally attains such a value that no further melting can take place. We then have a mixture of solid and liquid acetic acid in presence of each other under a measured pressure and at a known temperature. The quantities entering into the calculation are ascertained from other experiments—notably the ratio of the change of volume to heat absorbed was ingeniously ascertained by a modification of Bunsen's ice calorimeter. The final result was that the rate of variation of temperature of melting point with increasing pressure was calculated to be 0·02421° C. per atmosphere as against 0·02435° C. found by experiment, a difference of 0·57 per cent. I have dwelt on this work at some length in the hope that it may make the nature of the problem clear. It is to be noted that the experimental difficulties are considerable, and are enhanced by the fact that we have no *a priori* reason to suppose that the rate of change of melting point with pressure is a constant quantity independent of the pressure. In fact, it was shown by Sir Joseph Thomson about 1886[1] that in calculating the change of melting point we ought to take into consideration "the difference between the energy due to strains produced by the pressure in unit mass before and after solidification." Sir Joseph Thomson's reasoning, based as it is on a generalised Lagrangian method of treating problems involving energy changes, is unsuited for discussion in a non-mathematical address, but it is easy to see that if the compressibilities of liquid and solid are different, then the change of volume accompanying the change of state of unit mass must itself depend on the pressure, and therefore the pressure change of melting point, which is proportional to the change of volume, must depend on the square of the actual pressure so far as this part of the effect is concerned. This anticipation was realised by Damien in 1891, who showed that the melting points of substances in terms of the pressure could be expressed by a formula of the kind

$$t = t_0 + a(p-1) - b(p-1)^2,$$

t_0 being m.p. under 1 atmosphere pressure.

I think we may add that there will also be a small effect depending on changes of energy in the capillary layer separating the phases.

The first adequate investigation of the change of m.p. under pressure over a wide range of pressures was made by Barus.[2] Time does not permit me to do more than exhibit the results obtained, though the apparatus employed was most cleverly designed. It requires great experimental knowledge and ingenuity to infer with accuracy changes of volume of a few per cent. of the original volume at pressures of 1500 atmospheres, nearly ten tons per square inch. If we note the pressures and temperatures of melting, and plot the result as a curve against the pressure and temperature, we obtain what is called a melting-point curve, and this divides the field into two parts, so that on one side of the curve the temperature and pressure at each point have such values that the substance is solid, while on the other side their values are such that the substance is liquid. It is instructive, therefore, to regard the melting-point curve as the line separating the region of solid from the region of liquid. Along the line, and along it only, *i.e.* at the pressures and temperatures indicated by points on the line, the solid and liquid phases can exist in equilibrium together. Such a diagram is called a "diagram of condition."

[2] Bulletin No. 96 of the U.S.A. Geological Survey, 1892.

By far the greater part of our information as to the quantitative relations of bodies at high pressures we owe to Prof. Gustave Tammann, who has collected his results in a book entitled "Kristallisieren und Schmelzen," the advent of which (1903) must be regarded as an important event in the history of the subject.

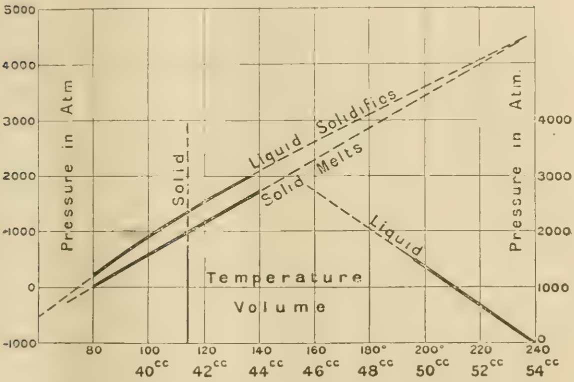

FIG. 1.—Full lines indicate part of field actually explored. Dotted lines indicate extrapolations.

The complete thermodynamic specification of a body involves a knowledge of its mass, volume, pressure, temperature, energy, entropy, surface tension, and nature, whether liquid, solid, glassy, crystalline, or amorphous.

Prof. Tammann has simultaneously measured the pressure, temperature, volume, and mass of many substances under high pressure, and at temperatures extending from 80° C. to 200° C.—taking cognisance of the physical state—and has thus been able to plot out many interesting diagrams of condition. The apparatus consists of a screw press by which a piston of ebonite is driven down a steel cylinder of small known cross-section. The cylinder is filled with oil, and the ebonite piston fits practically oil-tight. The oil communicates with the oil contained in a strong steel vessel, which also encloses a glass tube open at the lower end, containing the substance and dipping below the level of mercury contained in a dish. The oil occupies the rest of the space. The steel vessel is placed in a thermostat so that its temperature can be ascertained. The oil pressure is measured by a Bourdon gauge, which it was possible to standardise, thanks to the previous work of Amagat and Tait. In order to construct a diagram of condition, it is necessary and sufficient to find a number of points separating the liquid from the solid area, or separating the areas corresponding to different crystalline forms in the case where the transformation of one sort of crystal into another is under investigation. To understand how this is done, it is best to take a special case. If we have a quantity of a substance under a known pressure and temperature in the piezometer, and suddenly increase the pressure, so that there is not time for heat to pass in or out to any appreciable extent before the pressure gauge can be read, we have practically adiabatic compression. If the apparatus be then left to itself, the heat which we may suppose to be liberated by the pressure will slowly diffuse outwards, and the pressure will fall as time goes on. If we happen to start from a point on the m.p. curve before the pressure is raised, then the final result will be that we shall thaw or freeze more or less of the material, and the original pressure will be exactly regained, the change of state compensating the impressed change of volume. If, however, the increase of pressure has been so great that a change of state of the whole mass has been brought about, then the after variation of pressure will be so much greater that it is easy to distinguish this case from the previous one.

The accompanying diagram (Fig. 2), taken from Prof. Tammann's book, shows how the equilibrium curve can be located in the case of carbon dioxide and naphthalene. In the former case the temperature was 0·31° C. The pressure was 3800 kilograms per sq. cm., or 24·13 tons per sq. inch. (157·49 kilograms per sq. cm. = 1 ton per sq. inch = 152·38 atmospheres.)

The pressure was raised adiabatically to 4400 kg./cm.^{2} (27·93 tons/sq. inch), and the subsequent fall of pressure plotted against a time scale for ten minutes. The pressure was then adiabatically reduced to 3550 kg./cm.^{2}, and the recovery curve again plotted. The equilibrium pressure must lie between the pressures approached asymptotically on the diagram, *i.e.* between 3825 and 3792 kg./cm.^{2}. A repetition between narrower pressure limits enables the pressure to be fixed at between 3808 and 3797 kg./cm.^{2}. A similar procedure fixed the pressure of the m.p. of naphthalene between 3090 and 3080 kg./cm. at the temperature considered, a difference which corresponds to 0·2° C., the actual temperature possibly differing from the thermostat temperature by 0·1° C.

We may now pass on to the consideration of some of the results obtained, which refer, not only to change of melting points, but to changes in the temperatures of transformation of isomorphic forms.

As illustrations of such changes, I show here the transformation of yellow to red mercuric iodide, which shows well in the projection microscope; also Mitscherlich's transformation of potassium bichromate, and sulphur in two forms.[1]

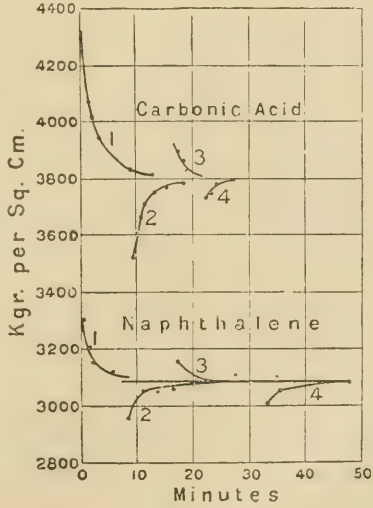

FIG. 2.

---

[1] *Experimental Demonstration of a Transformation of Sulphur.*—A microscope slide is prepared by partially melting a fragment of monoclinic sulphur, and enclosing some of the melt between the slide and cover-slip, well pressed together. The presence of unmelted monoclinic sulphur insures the crystallisation of this variety on lowering the temperature. By means of a hot stage it is possible to preserve the crystallisation long enough to exhibit it by means of a projection polarising microscope. The appearance is very characteristic. Another slide is prepared, but this time all the sulphur is melted, and can generally be undercooled so far that it crystallises in what

The case of sulphur is one of great interest. It has long been known that sulphur can exist in at least three solid forms. It crystallises from some solvents in octahedral crystals, from others or from its liquid state in monoclinic crystals. In the latter case some amorphous sulphur is generally dissolved in the crystals, and the amorphous variety itself is formed in tough vitreous masses when molten sulphur, heated until it becomes very viscous, is poured into cold water. At ordinary temperatures the octahedral form alone is stable. It has been found that at atmospheric pressure octahedral sulphur is converted into monoclinic at 95·4° C., and in the process 2·7 gram-calories per gram of sulphur are evolved. The density of octahedral sulphur is about 2·03 and of monoclinic about 1·98 at ordinary temperatures. In accordance with the principles developed previously, the transformation temperature of rhombic to monoclinic sulphur must rise with increase of pressure. So far back as 1887 Roozeboom[1] was able to predict that the diagram of condition for sulphur would be as shown in Fig. 3.

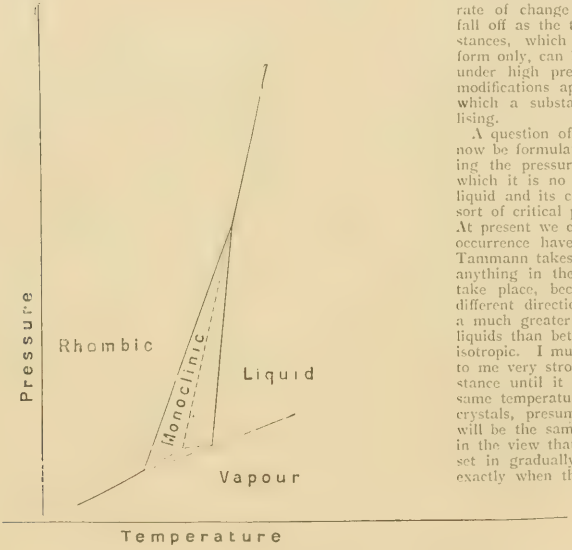

FIG. 3

Prof. Tammann has supplied the corroboration of the existence of the triple point.

Suppose that we have sulphur at a pressure of about 1500 kg./sq. cm. (9·52 tons/sq. inch) and raise its temperature to about 160° C. or more, we shall cut the melting-point curve of octahedral sulphur, and the sulphur will melt. If we then allow the sulphur to cool, keeping the pressure up, octahedral sulphur will crystallise from the melt instead of monoclinic sulphur. This very likely has some bearing on the occurrence of native crystals of octahedral sulphur.

It is not every substance which has such sharply defined properties as sulphur, though even these are not so sharp as they might be, owing to the constant presence of amorphous sulphur. An instructive case is afforded by phenol. As the diagram shows, there is a considerable region of the field in which two kinds of crystals of different density can exist together, the curves forming the boundary of this region of pseudo-equilibrium.

It may be that the two crystalline forms of carbon which apparently can exist together indefinitely at ordinary temperatures and pressures are an illustration of the same property.

As a final illustration we may note the results for water down to −80° C., from which it appears that it possesses three allotropic crystalline forms with at least two melting points.

The melting curves of from thirty to forty substances have been investigated, mainly by Tammann, up to about 3000 kg./sq. cm. = 19·05 tons/sq. inch, and the general result has been to show that there is a tendency for the rate of change of melting temperature with pressure to fall off as the temperature rises, and also that many substances, which at ordinary pressures crystallise in one form only, can be caused to assume allotropic modifications under high pressure. This tendency to form allotropic modifications appears to be associated with the extent to which a substance can be under-cooled without crystallising.

A question of the greatest interest and importance may now be formulated, What will happen if we go on increasing the pressure? Will a state of affairs be reached in which it is no longer possible to distinguish between the liquid and its crystalline form? Will there be, in fact, a sort of critical point at which the melting curve will end? At present we can only say that no indications of such an occurrence have been observed experimentally, and Prof. Tammann takes the point that it is highly improbable that anything in the nature of continuous transformation can take place, because a crystal has different properties in different directions related to its axes, and there is thus a much greater qualitative difference between crystals and liquids than between liquids and gases, both of which are isotropic. I must admit that this argument does not appeal to me very strongly. If it be possible to compress a substance until it reaches a state in which, at one and the same temperature, the liquid has the same density as the crystals, presumably the mean distance of the molecules will be the same in both cases. I see nothing monstrous in the view that in these circumstances crystallisation may set in gradually, and that it may not be possible to say exactly when the liquid ceases to be a fluid and becomes a crystalline solid. There are no theoretical or other grounds for supposing that the phenomena of crystal growth, as observed when there is a change of volume accompanying the crystal formation, will necessarily hold when no such change of volume occurs.

If we refer to the theory of the change of m.p. by pressure it is obvious that if either the change of volume or the latent heat of melting vanish at any temperature or pressure on the melting curve, then in the neighbourhood of this pressure the curve must degenerate to a point, or small pressure changes will not affect the m.p. It was pointed out, however, that there is a term or terms depending on the square of the pressure, and if these were relatively important the only thing we should notice would be a change of curvature at the point under consideration. It does not follow that there is no maximum or minimum to the melting temperature of any particular substance because the term in P^2 may be vanishingly small; it may be (and generally is) of opposite sign to the term in P, and in this case it is only a question of the relative importance of the terms where the maximum or minimum melting point lies. Damien's empirical formula expresses precisely the effect to which I refer. The practical result which is of importance in questions affecting the condition of the inner layers of the earth is that we are not entitled—in fact, it is wrong—to suppose that pressure must necessarily go on raising the melting point indefinitely; everything depends on the substance under con-

---

is believed to be the octahedral system. This slide is then placed in the projection microscope, when it is seen that its appearance is totally different from that of the first slide. The preparation of octahedral sulphur is then heated on the hot stage, and when the transformation temperature is reached it is seen that the structure begins to change—the crystallisation breaks up and becomes granular, the granules showing in general much more colour than the original crystallisation. These granules are taken to be monoclinic sulphur. The temperature is now raised until about half the preparation has melted, and it is then allowed to cool back a little so as to crystallise. The crystals now show the characteristic monoclinic crystallisation with brilliant colours, since unmelted monoclinic sulphur is present.

[1] Rec. Trav. Chim. Pays-Bas, vi., 1887, 314.

sideration. It is therefore necessary to make such experiments as those of Tammann at vastly higher temperatures and pressures than those we have been considering, up to probably more than 10,000 kilograms per sq. cm. (or 63·5 tons per sq. inch).

In 1893 some experiments were described by Parsons[1] in which carbon rods were heated by electricity under a pressure usually of 15 tons per sq. inch, but rising in one case to 30 tons per sq. inch. The pressure was obtained by means of a hydraulic press, but no detail is given.

I have been desirous for many years of making some experiments at high temperatures and pressures, but for a long time could think of no way of ascertaining the pressure at temperatures over a red heat except by the use of compressed gases. In 1902 Sir Andrew Noble was kind enough to have some drawings prepared for a wire-wound steel pressure vessel to carry a pressure of 50 tons per sq. inch. The pressure was to be supplied by a compressed gas, and some details of the heating arrangements were designed, when a calculation of the cost of the gas compressors, vessel and appurtenances, made it clear that the undertaking would be beyond my means. I then endeavoured to find a simpler form of apparatus, and finally was led to contemplate the substitution of graphite for compressed gas, Spring having pointed out that crystalline graphite flows very easily at high pressures. A simple trial made it clear that the graphite of Ceylon does, in fact, possess the property of flowing like a liquid under high pressure to a sufficient degree to allow of pressure being transmitted by it. Graphite can be used, with some reservations, to transmit a pressure just like water or oil, though it is, of course, inferior in fluidity, and, as I have now discovered, occasions a loss of "head" which is not independent of the pressure itself. My former statement in the Chemical Society's Journal, 1908, is erroneous, though the results of the experiments are, I believe, hardly, or not at all, affected by the mistake, for a reason which will be clear later on. After several trials, the apparatus which I have here to-night was evolved, and some experiments were made with it. These experiments are not of any great importance, and, indeed, I feel almost ashamed of bringing them to your notice—I can only say, in excuse, that everything must have a beginning.

I believe, however, that the apparatus is sufficiently simple, cheap, and effective to enable others with more leisure at their disposal to make a beginning of an investigation of the properties of matter up to 100 tons per sq. inch, and at temperatures up to about 2000° C. At present, however, it is not possible to infer with accuracy the volume of the substance under these extreme conditions, nor can its physical condition be more than approximately and indirectly inferred—we must content ourselves with the production of transformations which we can make persist down to ordinary temperatures and pressures.

If we refer again to the sulphur diagram, we shall see how this possibility may arise. If sulphur is melted and cooled slowly, monoclinic crystals are found—when the temperature sinks below 98° C. these crystals undergo spontaneous transformation to the rhombic form—but all that we see is that the monoclinic crystals become opaque; the external form of the crystals is still monoclinic, but they are merely pseudomorphs of the original crystals.

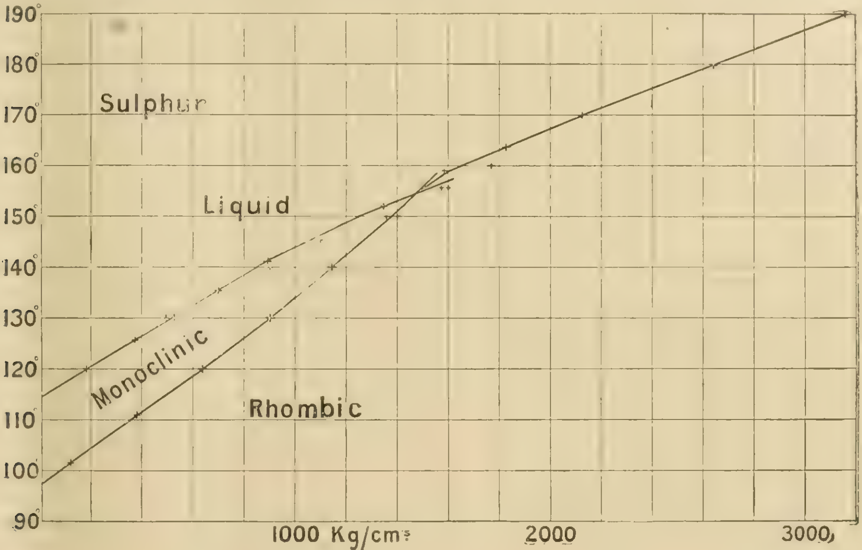

FIG. 4.

To obtain large octahedral crystals we may suppose that we begin by melting sulphur and raising the temperature and pressure until the former stands at 160° C. or over, and the latter at not less than 1600 kg./cm.^{2} (10·16 tons/sq. inch).

If we then slightly reduce the temperature or raise the pressure, we shall have the crystallisation of the sulphur in the rhombic form. By maintaining the pressure as the mass cools, and when it is cold releasing the pressure, we should finally extract rhombic crystals. To this we may, of course, add that we need not expect crystals of any size unless we cool at the proper rate. It appears that there are at least two phenomena requiring attention in relation to the production of crystals—one is the relation between the amount of undercooling necessary to induce spontaneous crystallisation, and the other is the rate at which the crystals will grow when they have once started. If we want large crystals we must not have an excessive number of points of spontaneous crystallisation, nor must we have too high a rate of crystal growth, or the crystals will by all experience tend to be felted together. 'The temperature condition giving birth to the most favourable number of spontaneous centres is not necessarily the temperature at which crystals grow to the largest size, so there is really no escape from finding by direct trial the most effective way to go to work.

---

[1] Phil. Mag., xxxvi., 504.

Another possibility is brought to light by an examination of a case of pseudo-equilibrium, such as that of phenol. Here we have three regions—in one No. 1 alone is stable, in another No. 2, and in the third both Nos. 1 and 2 are stable. The case of iodide of silver is similar but more complicated. If in the area C we change the pressure, the temperature remaining constant and the material consisting of a mixture of the two stable phases, we can alter the proportions in which these phases exist, but we cannot cause either of them to disappear.'

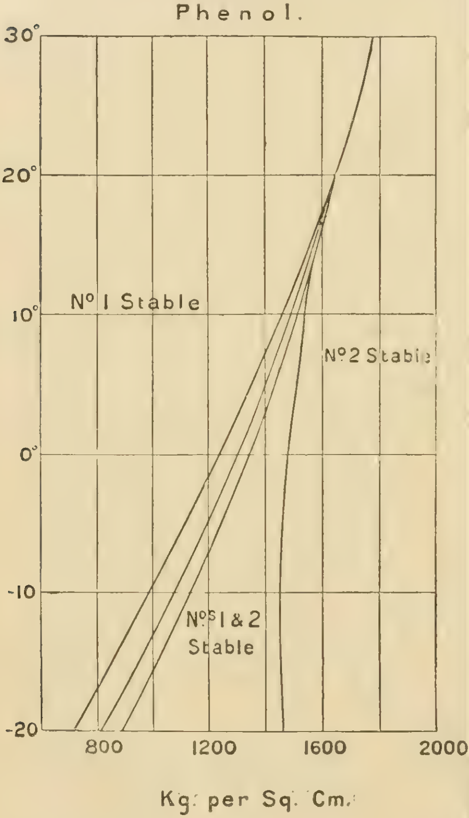

FIG. 5.

A notable case of this kind is that of graphite and diamond,' both perfectly stable in presence of each other at atmospheric pressure up to a temperature nearly that of the electric arc, say about 3000° C. If there be any similarity between the carbon and phenol diagrams, diamond would correspond to variety No. 2 of phenol and graphite to variety No. 1, heat being evolved in both cases when the less dense modification changes into the denser. If we desire to obtain phenol 2 from phenol 1, we note that, down to a temperature of −20° C., we should require to keep the pressure always above about 600 kg./cm.^{2}, otherwise the operations would be similar to those described in the case of rhombic sulphur.

Similarly, to convert graphite to diamond on this analogy we should have to raise the temperature and pressure together to some unknown values, and then let the product cool, keeping up the pressure meanwhile.

The apparatus which I have used in making the experiment is based on the transmission of pressure by crystalline graphite or the softer metals. In order to ascertain how much pressure is lost during transmission, I have arranged an apparatus in which the material to be tested is exposed to a known pressure, tending to force it through a cylindrical space, identical in figure with the space in which the heating is intended to be carried out. The pressure transmitted is transferred by a simple device to a piston with a hard steel point, and this is forced by the pressure to penetrate a soft steel plate. In a subsequent experiment the same piston is forced by a known pressure into the same steel plate so as to penetrate to the same depth as in the main experiment. It is then possible to compare the pressure transmitted with the pressure applied.

Experiments of this kind have been made with lead and with graphite as pressure-transmitting substances.

So far as I know, there is no substance other than graphite combining the property of a certain amount of fluidity with the capacity to resist high temperatures, and our hope of studying chemistry at really high pressures and temperatures appears at present to depend largely upon it. It is true that some attempts have been made to use compressed gases, but the apparatus is vastly more complicated, and the experiments themselves become really dangerous in view of the immense potential energy possessed by gases at pressures of 100 tons per square inch. As illustrating this, I may mention that 100 tons per square inch is about the highest instantaneous pressure noted by Sir Andrew Noble in his well-known experiments on the exploding of cordite in closed vessels. The density of nitrogen at 100 tons per square inch is, taking Boyle's law as a very rough approximation, 15,240 times its density under standard conditions. This works out to rather more than 19, *i.e.* about the same as gold, and the energy stored is of the same order as that contained in an equal volume of cordite, though its availability is lower.

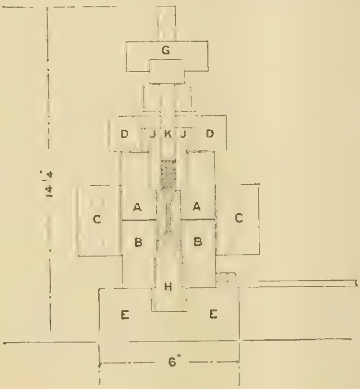

FIG. 6.

The construction of the apparatus I have used can be easily followed from the drawings. It consists essentially of a steel cylinder divided perpendicular to the longitudinal axis by a thin plate of mica, the two halves being clamped tightly together by an insulated ring and clamps at top and bottom. Pressure can be applied by an ordinary hydraulic lifting jack—the one I have used will lift fifty or sixty tons—the bore of the hydraulic cylinder being about 4½ inches. In order to operate at a high temperature it is necessary to line the cylinder with some refractory substance, and I have generally used magnesia for this purpose, though zirconia or thoria might be better. Purified magnesia is first melted in an electric furnace, and then ground in an iron mortar until it is very fine. The powder is freed from iron as well as possible by a strong magnet, and after being sifted is pressed into the cylinder little by little by hydraulic pressure so as to form a solid plug. This is then bored out with a hard steel drill to the required diameter. In pressing magnesia I have found that it is not possible to thoroughly consolidate the powder in greater thickness than a few millimetres, even under a pressure of 50 tons per square inch. In fact, magnesia is a substance which appears to be almost devoid of the fluid properties so marked in graphite—an essential condition for its use in the apparatus. I have tried various other linings, ground flint, alumina, &c., but they have no advantage over magnesia, and are even more difficult to drill out. Alumina prepared from the crystalline hydroxide is very easily compressed into cakes, and makes a good lining, but it is too fusible for experiments on carbon, and is probably more easily reduced. The cylinder having been lined, the bottom is filled in with Acheson graphite in electrical communication with the base of the apparatus. The substance to be operated upon is placed in the narrow part of the bore, and packed in with graphite or lead if that is suitable. The pressure is applied by a ram of hardened high-speed steel working upon a reservoir of graphite or lead contained in the plug closing the cylinder at the top and electrically connected to the other terminal of the supply. The chief uncertainty in regard to the pressure which actually reaches the subject of the experiment lies in the possibility of the ram being held to some extent by friction against the sides of the cylindrical hole in which it works, and in the consolidation of the graphite, with reduced fluidity, before it actually flows. One has to trust either to the hardness of the ram or to leave a space round it sufficient to allow graphite to escape, when the apparatus follows the lines of Amagat's standard pressure gauge, but the duration of the experiment is curtailed by the exhaustion of the graphite supply. A correction has to be applied for the pressure absorbed by the lead or graphite in accordance with the results of the preliminary trial. It is fair to say that no tendency of the ram to stick has ever been noticed—on the contrary, changes of volume brought about by heating have made themselves evident at once on the pressure gauge of the hydraulic press.

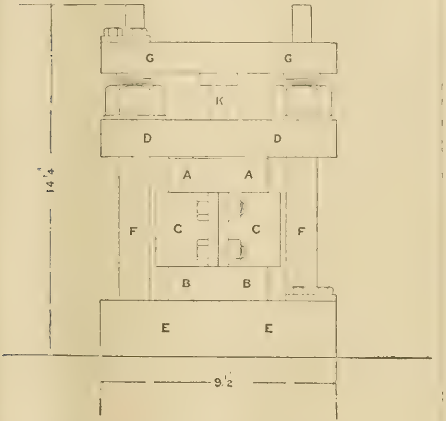

FIG. 7.

When working with any form of carbon there has been no trouble in arranging to heat the body which is being compressed by electrical means. It has been found most convenient to adjust the current to about the value required by means of a resistance—large compared with that of the pressure vessel—the latter being short-circuited meanwhile. In making an experiment, the hydraulic press is worked until the desired pressure is attained, and then by opening the switch the current is thrown on to the apparatus. When the magnesia lining begins to melt, the pressure, as shown by the pump gauge, is seen to fall, graphite flows into the magnesia tube, and the pump is worked so as to compensate for this. Under these conditions the pressure is probably transmitted without appreciable loss, as the narrow part of the cylinder is now in a fluid bath. After a sufficient time has been allowed the switch is closed, and the pressure kept up by pumping until the apparatus is cold. Originally an apparatus with a cylinder made in one piece was employed, and in this case there was a considerable voltage between the graphite entering the apparatus and the steel walls of the pressure vessel. After a few seconds of intense heating it frequently happened that an explosion took place, due (as could be seen by subsequent examination) to filaments of graphite being driven through the magnesia and producing short circuits against the steel vessel. With the construction above described these explosions do not occur, and there is the additional and very real advantage that when an experiment is over the apparatus can be opened in the middle and everything exposed to view.

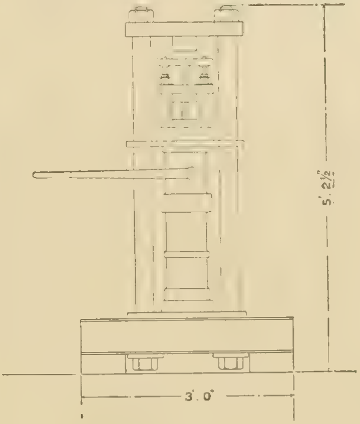

FIG. 8.

A large number of experiments were made on different kinds of carbon and graphite. The weight of material in the highly heated part was generally from 1 to 2 grams, and the energy supply was at a rate of 5 to 10 kilowatts for from three to six seconds. The pressure in a successful experiment lay at from 50 to 100 tons per square inch throughout. The magnesia lining was usually melted for a distance up to 1 centimetre round the graphite. Now magnesia melts at ordinary pressures at about 2000° C., but the energy supply is sufficient to render it possible that temperatures of from 3000° to 4000° C. may have been reached; it is possible that about 3000° C. was actually attained at the centre of the charge. The results obtained were uniform. No matter what form of carbon (excluding diamond, which was not tried) was packed originally in the apparatus, the final product was soft, well-crystallised graphite, which agrees with some results of similar experiments described by Mr. Parsons,[1] but not with the results claimed by Dr. Ludwig.[2]

In several experiments the crystalline mass of graphite was tested in regard to its porosity, and this was found to be considerable—a remarkable result, having in view the conditions under which it had been formed.

---

[1] Proc. R.S., 79.

[2] Zeits. f [illegible] 1902, 273

Another point of interest was that where the soft graphite had been driven into the Acheson graphite plug at the bottom of the apparatus it became extremely hard, so much so that a hard steel file made little or no impression upon it.

The main difference in treatment of this part of the graphite as compared with the remainder is that it was cooled much more quickly, thanks to the high heat conductivity of the Acheson graphite plug. The cause of hardening has hitherto not met with any satisfactory explanation.

No appreciable quantity of carbide of magnesia was formed in the experiments. The magnesia close to the graphite core contained traces of carbides, but as there were always traces of iron left from the drilling-out process, this may be plausibly accounted for by the formation of carbide of iron.

The graphite was finally systematically searched for microscopic diamonds by Staudenmaier's modification of Brodie's method of conversion of graphite into graphitic acid,[1] or else by Moissan's modification of the same method.[2] A convenient means of distinguishing diamond in fine powder from most or all of the substances which are not separated by a liquid of density 3·34 at 4° C. is to heat the powder in a silver spoon to a dull red heat in fused potassium hydroxide. Check experiments showed that diamond dust easily passing a sieve with 100 threads to the inch would withstand the action of molten caustic potash at a temperature at which the edges of the silver spoon began to melt for five or ten minutes. Crystals of alumina or of carborundum are entirely destroyed by this fusion, but the diamond particles seemed to have undergone no change. In fact, the individual fragments could be recognised under the microscope after passing through the ordeal.

I am led to consider that my experiments indicate that no wholesale transformation of amorphous carbon or graphite into diamond can be brought about by temperatures of the order of 2000° C. and pressures of more than 50 and less than 100 tons per square inch. There is some uncertainty, as already mentioned, in regard to the actual pressures operative during the trials. Prof. Tammann has, however, obligingly directed my attention to the fact that the equilibrium curve graphite-diamond may nevertheless have been crossed, but that no diamond was formed because time for crystallisation was not allowed under the conditions of the experiment. I confess my idea in making the trials was that the amorphous carbon or graphite might be forced to melt, and then that the conditions would require it to re-crystallise as diamond—not, of course, in the form of large clear crystals, but rather in the form of bort or black diamond.

The experiments described have only been rendered possible by the invention of high-speed steel, which keeps its hardness up to nearly, or quite, a red heat, and any further advance—mainly in the direction of the allowance of more time—must wait for improvements in that material. It may very well be, however, that the limits of temperature within which crystallisation in diamond form can take place are really very narrow at any pressure; and in this case it will be a matter of very great difficulty to make an apparatus in which the conditions could be kept constant for a sufficient length of time, and the difficulty would be greater the higher the temperature.

It is noteworthy from this point of view that in Moissan's artificial production of diamond very much lower pressures and temperatures were used than those just described. I have shown[3] that, using iron as a solvent, it is highly improbable that Moissan attained a pressure of more than 20 tons/sq. inch, and when silver was employed the pressure must have been much lower. A similar criticism places the effective temperature of formation of diamond in iron or silver spheroids at something of the order of 1500° C. Comparing the experiments of Moissan with those described above, it looks as if Roozeboom's opinion is at present the most probable, viz. that solvents are necessary in order to depress the crystallisation point of diamond to a temperature at which the transformation to graphite is slow enough for rapid cooling to interrupt it. In this case the next step would be to repeat the experiments I have described at the highest possible pressure in the presence of iron, though Mr. Parsons[1] has already made some trials in this direction with negative results. We have, however, many metals which have never been tried in this connection, and one or other of them may turn out to have the requisite properties.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The board of anthropological studies has elected Mr. A. R. Brown, fellow of Trinity College, to the Anthony Wilkin studentship in ethnology and archæology. The John Winbolt prize has been awarded to Mr. E. T. Busk, of King's College.

A university lectureship in zoology, recently held by Prof. Gardiner, is now vacant. The general board of studies will shortly proceed to appoint a lecturer to hold office from January 1, 1910, until September 30, 1914. The annual stipend is 50*l*. Candidates are requested to send their applications, with testimonials if they think fit, to the Vice-Chancellor on or before Saturday, November 27.

The Vice-Chancellor gives notice, on behalf of the board of geographical studies, that the Rev. T. G. Bonney, F.R.S., has consented to deliver a lecture in Cambridge on Thursday, November 25, at 5 p.m., on "A Desert Phase in the Development of Britain." By permission of Prof. Hughes the lecture, which will be illustrated by lantern-slides, will be given in the large lecture-room of the Sedgwick Museum of Geology.

The professor of botany also gives notice that Dr. H. H. W. Pearson, of Gonville and Caius College (professor of botany in the South African College, Cape Town), has consented to deliver a lecture at the Botany School on Friday, November 19, at 5 p.m., on "A Botanical Journey in South-west Africa."

The general board of studies has approved Dr. C. S. Myers, of Gonville and Caius College, and A. E. Western, of Trinity College, for the degree of Doctor in Science.

LIVERPOOL.—Mr. W. S. Abell, instructor in naval architecture at the Royal Naval College, Greenwich, has been appointed to the chair of naval architecture endowed by Mr. Alexander Elder.

OXFORD.—Mr. Balfour will deliver the Romanes lecture in the Sheldonian Theatre on Wednesday, November 24. Lord Curzon of Kedleston, Chancellor of the University, will preside.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 11.—Sir Archibald Geikie, K.C.B., president, in the chair.—H. C. **Ross**: The vacuolation of the blood-platelets: an experimental proof of their cellular nature.—H. G. **Plimmer** and Captain W. B. **Fry**: Further results of the experimental treatment of trypanosomiasis, being a progress report to a committee of the Royal Society.—G. S. **West** and B. M. **Griffiths**: *Hillhousia mirabilis*, a giant sulphur bacterium.—Dr. H. B. **Fantham** and Miss Annie **Porter**: The modes of division of *Spirochaeta recurrentis* and *S. duttoni* as observed in the living organisms. The observations recorded were made on living Spirochætes. The examination of living material is imperative, as results based only on stained preparations are not always trustworthy. Both longitudinal and transverse division occur in Spirochætes, as seen in *S. recurrentis, S. duttoni, S. anodontae*, and *S. balbianii*. There is a periodicity in the direction of division exhibited by *S. recurrentis* and *S. duttoni*. At the onset of infection longitudinal division occurs. This is followed by transverse division of the

Spirochætes when the infection is at its height. As the infection draws to an end, and there is a diminution in numbers of the parasites, there is a reappearance of longitudinal division. Naturally there are times when both forms of division occur together. The observations relating to periodicity were made on peripheral blood of the host. The actual processes of division, and the movements of the parasites meanwhile, are set forth in detail in the paper.—G. A. **Buckmaster** and J. A. **Gardner**: The supposed presence of carbon monoxide in normal blood, and in the blood of animals anæsthetised with chloroform. In a paper published in 1898, Desgrez and Nicloux stated that the normal blood of Paris dogs contains about 1·6 c.c. of carbon monoxide per litre, and that when the animals are anæsthetised by chloroform the amount increases to 2·5 to 6 c.c., according to the duration of anæsthesia. Their method of estimating carbon monoxide consisted in passing the blood gases over iodine pentoxide at 150° C., and determining the iodine liberated by the method of Rabourdin. The authors have carefully re-investigated the question, making use of Haldane's method of estimating carbon monoxide by means of diluted blood, after having previously ascertained that far smaller quantities of this gas than those found by the French observers in normal blood gases could be readily detected. They find that *neither normal cats' blood nor the blood of cats anaesthetised by chloroform contains any detectable trace of carbon monoxide.* They also find that most of the chloroform in the blood comes off with the gases when extracted at 40° C. In order to arrive at an explanation of Nicloux's results, the authors (1) repeated his experiments with variations, investigated (2) the effect of heat on iodine pentoxide, (3) the effect of chloroform vapour on iodine pentoxide, and (4) the effect of chloroform vapour on alkalis. The latter experiments show that chloroform vapour is readily decomposed by passing over solid potash, and also by the reagents used in gas analysis, with the production of carbon monoxide. It is concluded from the experiments (1) that chloroform is not decomposed in the blood with formation of carbon monoxide; (2) the iodine liberated in the experiments of Nicloux was due, to some extent, to the direct decomposition of the iodine pentoxide by the chloroform vapour in his blood gases, but mainly to the carbon monoxide produced by *the action of this chloroform on the solid potash over which he passed the blood gases* in order to free them from carbon dioxide.—G. W. **Ellis** and J. A. **Gardner**: The origin and destiny of cholesterol in the animal organisms. Part vi., the excretion of cholesterol by the cat. In this paper the results of a number of estimations of the cholesterol content of the fæces of cats fed on a variety of diets—animal and vegetable—of known cholesterol content, are described. It was found that cats behave similarly to dogs when fed on meat diets, but the tendency for the change of cholesterol into coprosterol appears to be greater in the case of cats. The change is, however, never complete unless the diet contains a considerable amount of fat. In all these experiments the total cholesterol and coprosterol excreted was considerably less than that taken in with the food. Without considering the cholesterol poured into the gut with the bile, the percentage deficit was 50–60, an average loss of about 0·08 gram per day. In the case of vegetable diets free from cholesterol or phytosterol, the weights of food necessary to keep the animals in condition were larger, and the amounts of fæces very much larger, than in the case of meat diets. Small amounts of cholesterol were excreted, averaging about 0·03 gram per day, but no change into coprosterol took place. In the case of artificial diets to which measured quantities of cholesterol or phytosterol were added, no excess of cholesterol above that administered was recovered from the fæces. The bearing of these results on hypotheses advanced in former papers of the series is discussed.—Prof. W. A. **Osborne**: The elasticity of rubber balloons and hollow viscera (with a note by W. Sutherland).

Manchester.

Literary and Philosophical Society, October 19.—Mr. Francis Jones, president, in the chair.—L. E. **Adams**: Some notes on the breeding habits of the common mole. An account was given of observations on the length of time the young of the mole spend in the nest, and their rate of growth. Special breeding nests, sometimes as large as, but generally simpler than, the winter fortresses, from which they are further distinguished by the absence of a "bolt-run," are made by the female for the accommodation of the young. These are usually born about the middle of May, though they have been observed as early as April 24, the latest date on which they were found in the nest being June 25. The author thinks that, considering their subterranean existence, climatic changes have little influence on their pairing early or late. Fresh observations confirm the statement made in a former paper that only one litter is produced annually by each pair. In any given season all the litters were born within a period of three weeks, and, as the young remain four weeks in the nest, there could not have been time to rear two litters. In order to ascertain the rate of growth of the young, the author took one, for measurement and reference, from each of several litters, and, after replacing the nest as carefully as possible, repeated the operation at intervals of a few days. The tabulated results showed that head and body measured at birth 40 mm., and at the end of the third week 117 or 118 mm., at which limit they evidently remained for some weeks before growth recommenced. The young begin to leave the nest at the end of the fourth week, and the process is a gradual one, requiring for its accomplishment six or seven days.

Paris.

Academy of Sciences, November 8.—M. Bouchard in the chair.—G. **Bigourdan**: A means of removing astronomical clocks from the influence of the variations of atmospheric pressure. The apparatus described and figured maintains the pressure round the clock constant, this pressure being fixed so that it is always higher than any possible atmospheric pressure.—L. **Maquenne** and M. **Demoussy**: The influence of the ultra-violet rays on the growth of green plants. The ultra-violet rays were produced by means of a Heraeus quartz mercury lamp. It was found that the ultra-violet rays determine the death of plant cells in a relatively short space of time, comparable with that required for the sterilisation of a contaminated liquid. The action is especially on the surface. —A. **Calmette** and L. **Massol**: The precipitation of the tuberculins by the serum of animals immunised against tuberculosis. In a preceding note a description has been given of a method of immunising cattle against tuberculosis by the injection of bovine bacilli cultivated on glycerinated ox bile. This method furnishes a serum of extraordinary agglutinating power. In the present note the precipitation of tuberculin from physiological saline solutions by this serum is described, and the properties of the precipitated tuberculin discussed.—M. **Giacobini**: Observations of Halley's comet, made at the Paris Observatory with the 38-cm. equatorial. Details of the observations on November 5, 6, and 7 are given. The comet is at the extreme limit of visibility; a small nucleus of the fourteenth magnitude can be distinguished, surrounded by a nebulosity of about 5″ to 6″.—Arthur R. **Hinks**: The mass of the moon deduced from photographic observations of the planet Eros, made in the years 1900 and 1901.—Eugène **Fabry**: The modulus of a Taylor's series.—E. **Vessiot**: The groups of rationality of systems of ordinary differential equations.—Demetrius **Gravé**: An identity in the theory of binary quadratic forms.—H. **Pellat**: A compound pendulum of very simple construction giving immediately the length of the synchronous pendulum. A new method of determining *g*. A description of a bifilar pendulum the bob of which contains a cavity. Two determinations of the time of oscillation are made, in one of which the mass is altered by the addition of mercury to the cavity. A simple calculation gives the length of the equivalent simple pendulum.—L. **Bloch**: The phosphorescence and oxidation of arsenic. The phosphorescence of arsenic is always accompanied by the production of the oxide. No ozone is produced, and there are no phenomena of ionisation. Both the oxides of arsenic are produced, and this is the case during both phosphorescence and during combustion with flame.—C. **Féry** and C. **Chéneveau**: The total and monochromatic radiation of incandescent lamps. A study of the relation between temperature of the filament and watts consumed by the carbon and tungsten incandescent lamps.—Georges **Claude**: The frigorific recuperation of volatile liquids lost in various industries. In many industries, especially in the manufacture of artificial silk, smokeless powder and celluloid, considerable quantities of alcohol and ether are lost owing to the enormous dilution with air. A practical system is described in which the air containing these volatile vapours is compressed and gradually cooled by expansion to a temperature of −100° C., a special device being necessary for the preliminary separation of the water. The method is shown to be capable of effecting large economies in practice.—E. **Rengade**: The theoretical form of the cooling curves of binary mixtures.—Marcel **Delépine**: The metallic iridio-sulphates.—A. **Guyot**: New general methods for the synthesis of aromatic aldehydes. The method is based on the condensation of a phenol, hydrocarbon, or amine with the $\alpha\beta$-diketonic esters of the type $X—CO—CO—CO_2R$.—Charles **Mauguin**: The acid properties of the halogen amides: the Hofmann migration. The sodium derivative of bromacetamide, $CH_3CO.NaBr$, has been isolated and its decompositions studied.—N. **Danaila**: The oxidation of the dimethylanilinisatins.—H. **Masson**: The composition of essence of cloves. To the principal constituents already known of essence of cloves it is necessary to add methyl salicylate and two aldehydes, α-methylfurfural and a dimethylfurfural.—P. A. **Dangeard**: The photographic properties of *Chlorella vulgaris*.—M. **Biot**: Concerning *Trypanosoma lewisi*.—M. **Glover**: The examination of the respiration and the graphical analysis of speech in special schools. The radioscopic examination of the thorax has been found of great value in examining the mode of breathing.—Paul **Hallez**: The biological cycle of a form nearly related to Otoplana.—P. **Hachet-Souplet**: The psychology of the Artiozoa.—Mlle. L. **Chevroton** and F. **Vlès**: The kinematics of the segmentation of the egg and the chronophotography of the development of the sea-urchin. An application of the method of Marey to the study of the embryonic development of an animal. A series of photographs is taken at equal intervals of time, and the long film, containing 7000 to 8000 images, examined in the kinematograph.—M. **Sarthou**: The presence in milk of an anæroxydase and a catalase.—M. **Billon-Daguerre**: A mode of integral sterilisation of liquids by radiations of very short wave-length. Geissler tubes, made of quartz, containing rarefied gases, give out rays of short wavelength which are twenty-five times more powerful in producing sterilisation than ordinary ultra-violet rays. Such tubes are more economical than mercury vapour lamps, requiring a primary current of 2 amperes at 4 to 6 volts.—E. **Gley**: The action of toxic serums and their antitoxins on the nervous system. Contribution to the study of the mechanism of immunity.—E. **Gley** and V. **Pachon**: The action of toxic serums on the isolated heart of animals immunised against these serums.

DIARY OF SOCIETIES.

THURSDAY, November 18.

Royal Society, at 4.30.—Bakerian Lecture: The Statistical and Thermodynamical Relations of Radiant Energy: Sir J. Larmor, Sec.R.S.

Linnean Society, at 8.—A New Tipulid Subfamily: W. Wesché.—Freshwater Rhizopods from the English Lake District: J. W. Brown.

Institution of Mining and Metallurgy, at 8.—The Development of Heavy Gravitation Stamps: W. A. Caldecott.—Experiments in Reverberatory Practice at Cananea, Mexico: L. D. Ricketts.

FRIDAY, November 19.

Institution of Mechanical Engineers, at 8.—An Internal-combustion Pump and other Applications of a New Principle: Herbert A. Humphrey.

MONDAY, November 22.

Royal Geographical Society, at 8.30.—A Naturalist's Travels on the Congo-Zambezi Watershed: S. A. Neave.

TUESDAY, November 23.

Institution of Civil Engineers, at 8.—*Further discussion*: The Single-phase Electrification of the Heysham, Morecambe and Lancaster Branch of the Midland Railway: J. Dalziel and J. Sayers.—The Equipment and Working-results of the Mersey Railway under Steam and under Electric Traction: J. Shaw.—The Effect of Electrical Operation on the Permanent-way Maintenance of Railways, as Illustrated on the Tynemouth Branches of the North-Eastern Railway: Dr. C. A. Harrison.

Zoological Society, at 8.30.

WEDNESDAY, November 24.

Royal Society of Arts, at 8.—Photo-Telegraphy: T. Thorne Baker.

British Astronomical Association, at 5.

THURSDAY, November 25.

Royal Society, at 4.30.—*Probable Papers*: On the Change in Hue of Spectrum Colours by Dilution with White Light: Sir William de W. Abney, K.C.B., F.R.S.—On the Nature of the Hydrogen Flocculi and their Structure at Different Levels in the Solar Atmosphere: Prof. G. E. Hale, For.Mem.R.S. and F. Ellerman.—The Boiling Point of Sulphur corrected by Reference to New Observations on the Absolute Expansion of Mercury: Prof. H. L. Callendar, F.R.S., and H. Moss.—(1) On the Refraction and Dispersion of Neon; (2) On the Refraction and Dispersion of Air, Oxygen, Hydrogen, and Nitrogen; (3) On the Refraction and Dispersion of Sulphur Dioxide and Hydrogen Sulphide, and their Relation to those of their Constituents: C. Cuthbertson and M. Cuthbertson.—On Flapping Flight: Prof. M. F. Fitzgerald.—The Crystalline Structure of Iron at High Temperatures: W. Rosenhain and J. C. W. Humfrey.—The Relation of Thallium to the Alkali Metals: a Study of Thallium-zinc Sulphate and Selenate: Dr. A. E. H. Tutton, F.R.S.—And other papers.

Institution of Electrical Engineers, at 8.—The Present Aspects of Electric Lighting: H. W. Handcock and A. H. Dykes.

FRIDAY, November 26.

Physical Society, at 5.—The Effective Resistance and Inductance of a Helical Coil: Dr. J. W. Nicholson.—Ductile Materials under Combined Stress: W. A. Scoble.—The Recoil of Radium C from Radium B: Dr. W. Makower and Dr. Sidney Russ.—The Sun's Motion with Respect to the Æther: Dr. C. V. Burton.

THE "ORIGIN OF SPECIES" AND ITS LESSONS.

Charles Darwin and the Origin of Species; Addresses, &c., in America and England in the Year of the Two Anniversaries. By Prof. E. B. Poulton, F.R.S. Pp. xvi+280 and index. (London: Longmans, Green and Co., 1909.)

ON November 24, 1859, appeared the first edition of that immortal work—the outcome of twenty years' research—which was destined to revolutionise scientific thought, first in the domain of organic nature, and ultimately in every department of intellectual activity. The celebrations of the jubilee of this publication and of the centenary of the birth of its illustrious author, held at Baltimore in January, at Oxford in February, and at Cambridge in June of the present year, have been the means of directing public attention in such detail and in such forcible terms to the magnitude of Darwin's achievements and to the far-reaching consequences of his labours that it may well be doubted whether any further tribute can be paid to the memory of our great countryman. Nevertheless, on the present occasion, practically coincident with the fiftieth anniversary of the publication of the "Origin," it is only appropriate that we should direct attention in these columns to the latest contribution to Darwinian literature, the above work by Prof. Poulton, which the author has happily contrived to issue on the exact date of the anniversary. The readers of NATURE may be reminded that in these pages, to which Darwin himself was a rare contributor, some of the greatest questions raised by the publication of the "Origin" have been fought out by the leaders of science in that field of natural knowledge which, at the touch of what Helmholtz designated the "new creative thought," became reduced from a state of chaos to one of scientific order.

Of that generation of naturalists who were active workers before the publication of Darwin's book, there are but few survivors. Alfred Russel Wallace, to whom the present volume is appropriately dedicated, Sir Joseph Hooker and Sir Francis Galton are happily with us. But the later generations, who have been taught to accept organic evolution as an established doctrine, are apt to overlook the extent of their indebtedness to that memorable publication of Darwin's half a century ago. Before the appearance of that work the group of sciences now comprised under the general term Biology were still under the thraldom of an ancient cosmogony from which the physical sciences had been emancipated, if not completely at least to a very large extent. The year 1859 marked the beginning of what may fairly be described as the Reformation Period of biological science. At some future period, when the progress of knowledge shall have enabled a still later generation to obtain a just perspective of the bearing of Darwin's work upon the current thought of his time, a re-publication of some of the arguments that were urged against his teachings will furnish most instructive material for the historian of science. What impression would be produced now, for example, by a critic who in a scientific journal gravely opened an attack upon the "Origin of Species" with the remark:—

> "It will not be denied, we presume, that animals were created for the use of mankind. Man was to have dominion over them" (Edinburgh New Philosophical Journal, 1860, vol. xi., p. 283).

The reviewer concludes with a general appeal to the churches to unite in demolishing the new heresy.

The work now under consideration which has prompted the foregoing retrospection is by an author so well known as one of the soundest of the modern interpreters of Darwinism that a brief summary of its contents will suffice to commend the book to the serious consideration of all naturalists. More especially do we commend this, as also Prof. Poulton's other writings, to those who have caught up the cry, popular in some circles, that although evolution is established Darwinism is dead, or, to quote from the preface, to those who "recognize a prophet in every reed shaken with the wind." Of the seven chapters in this new memorial volume, the first ("Fifty Years of Darwinism") is revised and extended from the address given at the centenary in Baltimore in January; the second ("The Personality of Charles Darwin") is compiled from notes of a speech delivered on the same occasion; the third gives an account of the centenary celebration at Oxford and the speeches made on that occasion; the fourth gives the speech delivered by the author at the banquet at Cambridge in June, and the fifth ("The Value of Colour in the Struggle for Life") is reprinted from the Cambridge memorial volume, which was noticed in these columns at the time of the international celebration last June vol. lxxx., p. 481). Chapter vi., which will be new to most of our readers, is on the mimicry in the butterflies of North America, and is compiled from notes of the anniversary address delivered to the Entomological Society of America at Baltimore in December, 1908. The seventh chapter contains a number of letters written by Darwin to Mr. Roland Trimen and hitherto unpublished. As with all Darwin's correspondence, it is perhaps hardly necessary to say that these letters will be found most delightful reading, and their interest is enhanced by Mr. Trimen's own reminiscences of Darwin and by the recording of the most severe and perhaps the only severe thing that our magnanimous leader ever said of a scientific contemporary.[1]

In addition to these chapters, there are four appendices which are by no means the least interesting sections of the work. In the first of these, Darwin's views on the hypothesis of multiple origins are summarised, and in the second his conclusions with respect to what are now called "mutations" are marshalled in systematic order, and leave no doubt that this mode of evolution had over and over again been considered by him and always rejected as a *modus operandi* in nature. The mutation theory is happily paraphrased by Prof. Poulton in the preface as "based on the conception of an inborn transforming force violently discharged at regular intervals by every species of times past, present and to come"—a view on all fours with that upheld by the late Duke of Argyll, and which formed the subject of a criticism in these columns by the present writer at the time of its promulgation ten years ago (vol. lix., p. 217). It is the old "internal developmental force" let off sporadically instead of continuously, only subject, according to the founder of the theory, to control by natural selection.

---

[1] The remark referred to (p. 28, note) is quoted from Prof. Poulton's article in the *Quarterly Review* of last July.

In the third appendix, as in his Oxford speech, the author refutes once and for all the absurd and unwarrantable conclusions respecting the mental degeneration due to the exclusive pursuit of science which certain writers have based upon Darwin's description of his declining artistic faculties with the advance of age. The last appendix is particularly striking, as it brings out for the first time a remarkable discrepancy between the views of the founder of the modern theory of mutation (de Vries) and certain English supporters of that theory (Bateson and Punnett) respecting the fundamental question of the transmissibility by inheritance of individual differences or "fluctuations." According to de Vries these fluctuations are transmissible; if they are not, the whole fabric of the Darwinian theory is, it is needless to point out, overturned. The elucidation of this point seems to be one of the most urgent problems awaiting attack by experiment.

The valuable contributions to the Darwinian theory with which the author of the present work has been for so many years identified have been mainly in that most fascinating field of the relationship between the colours of animals and their environment—a subject which first led the present writer to the serious study of the "Origin of Species" more than thirty years ago. In this class of phenomena, adaptation is obvious to those who do not wilfully close their eyes to the evidence. If this adaptation is not explicable by natural selection, then that principle can be applicable in no other department of organic nature. It is not going too far to say that with the proof or disproof of the utility of these resemblances in colour, form, pattern and habit which are so abundant in the insect world, the whole question of the validity of the Darwinian theory is bound up. Darwin himself foreshadowed this application; so also did Wallace. Bates, Wallace, and Roland Trimen applied it to mimetic resemblances, Thomas Belt was a contributor, and Fritz Müller in 1879 gave us a new and important lead. Its application to the development and use of the markings of caterpillars was among the early and by no means least important of the contributions to biological science by August Weismann. No writer in modern times has done more than Prof. Poulton to place this application of Darwin's theory upon a sound scientific basis, and not the least interesting of his contributions is to be found in the sixth chapter of the present work, wherein he traces with masterly hand the mimetic influence exerted by certain Old World butterflies upon the insects of the New World into which they are comparatively recent immigrants. Such a clear case as this, in which the direction of modification is not open to doubt, disposes at once of the theory that similar environmental influences produce similarity of colour and pattern, for here it is the old inhabitants of the country and not the later immigrants that have been modified in the direction of mimetic resemblance.

It may be permissible on the present occasion to extend one's contemplation of the book immediately under notice to certain wider considerations which arise from the work which has for so many years been carried out in the Hope Department of the University of Oxford. That work bears throughout the stamp of Darwin's influence, and stands as living testimony that the central doctrine proclaimed in the "Origin of Species" half a century ago is still a vitalising power. It will not be considered presumptuous to recommend to a generation which has been told that the species question is not even ripe for discussion a critical re-perusal of Darwin's classic. Thereby it will be made evident that for the author of that work, nature was a living whole—a frame of mind from which modern specialisation is unfortunately leading many of the younger workers astray. The breadth of view which enabled the author of the "Origin" to mould whole branches of science into his service must for all time be a matter for admiration and wonderment. How comprehensive that view really is may be inferred from the circumstance that there is scarcely one modern development of the species question—perhaps none with the exception of the long neglected work of Mendel—which in principle, if not in detail, is not foreshadowed in the "Origin." Even the all-important question of the transmission of acquired characters appears to have been raised, and to have been considered by Darwin, as may be gathered from an apparently forgotten passage in the "Origin" to which the writer has directed Prof. Poulton's attention, and which is quoted fully in the last appendix to the volume under consideration (p. 273).

Some other lessons conveyed by Darwin's "Origin of Species" may perhaps be worthy of consideration at the present time. We have heard much of late years about the want of public interest in science being due to the technical and popularly unintelligible language in which investigators express their results. The answer to that charge can best be given by pointing to Darwin's writings as a whole; these, although scientific in the technical sense, being nevertheless popular in treatment and commanding a sale never before realised by any set of treatises on purely scientific subjects. From this experience it is fair to conclude that unintelligibility is at any rate not a necessary accompaniment of sound scientific exposition.

The tendency to specialisation which is becoming more and more characteristic of modern scientific work is not in itself an unhealthy sign. It is the necessary consequence of the growth of knowledge on the one hand and of the limitation of the human intellect on the other. All the good work turned out by our investigators at the present time is the result of such specialisation. As time goes on, the increase in the mass of material and in the number of workers must reduce still further the limits within which the individual worker can hope to make substantial contributions to the knowledge of his subject. The danger to be guarded against is the unhealthy development of the effects of specialisation. Although it may no longer be possible to obtain a comprehensive grasp of a whole group of sciences, there still remains the lesson conveyed to the scientific world by Charles Darwin's work—that extreme concentration upon one particular investigation need not produce mental atrophy in other directions. There may be a narrowness of outlook produced by extreme specialisation which, if not guarded against, may easily pass from mere narrowness to actual illiberality of mind. This in its way is quite as unscientific, as it is certainly more dangerous in its immediate effect upon our younger contemporaries, as the shallowness arising from too great a diffusiveness.

R. Meldola.

ALPINE HYDROLOGY.

Service d'Études des grandes Forces hydrauliques (Région des Alpes.) Tome iii. Résultats des Etudes et Travaux au 31 Décembre, 1907. Pp. 688; with maps, photographs, and diagrams. (French Ministry of Agriculture, 1908.)

IN May of last year (vol. lxxviii., No. 2010) there were reviewed in these columns two volumes rendering an account of the initiation of a hydrological service in France, formed for the purpose of studying the rivers and watercourses of that country, which were capable of developing power for, and otherwise benefitting, industrial and agricultural pursuits. The purview of the inquiry was to be restricted, in the first instance, to the region of the Alps, to be extended later to the Pyrenees, and ultimately, no doubt, to include the Vosges and the hilly districts of the north and west. At the time of the issue of the volumes in question, the results of these investigations were only forthcoming in systematised form so far as the close of the year 1905, and operations had been confined to a certain portion of the Alpine watershed, the work being carried out under the supervision of two engineers, MM. de la Brosse and Tavernier, the former of whom reported on the basins of the Arve and the Isère, and the latter on the regions of the Durance and the Var.

The book before us is the third volume of the series, and it forms a compendium of figures and statistics no less impressive than its predecessors. It continues the account of the studies prosecuted by M. de la Brosse during the years 1906 and 1907. These relate to the northern district of the Alps, included between the bed of the Rhone and the Italian frontier on the one part, the Lake of Geneva and the basin of the Durance on the other part.

The southern district, from the basin of the Durance to the Mediterranean littoral, under the direction of M. Tavernier, is to form the subject of a subsequent volume.

M. de la Brosse commences his report with an enumeration of the gauging stations within his district of 26,000 square kilometres (10,000 square miles), showing that they have increased in number from 30 in 1903 to 60 in 1905, and to 100 at the present time. The number of separate gaugings taken in 1907 was more than a thousand. Nearly all the stations, he remarks, are of the foot-bridge type, the exceptions being in watercourses of considerable width, where barges were employed, and in places of considerable difficulty of access, where the only available method was to employ a skiff suspended from a cable fixed at some suitable level. The footbridge, from its greater security and convenience, proved by far the best system, and a number of interesting photographs show the variations in design at different stations to meet local peculiarities.

The instruments used for gauging were described in some detail in the first volume, and the only comments now made in connection with them, after some experience of their working, relate to a few trifling modifications and minor improvements in design. A calibrating station for testing current-meters was established at Grenoble in 1906, and this has been found a considerable convenience, as, prior thereto, the instruments had to be dispatched to the hydrotechnical laboratories of Berne or Munich.

The station in question comprises an electrical apparatus, mounted on a framed platform, set in a quiescent sheet of water forming part of a fortification moat. The apparatus is actuated by a triphase motor of 5 horse-power, which enables various degrees of speed to be imparted to a movable arm carrying the instrument to be tested, ranging from a few centimetres to nearly 5 metres (say, an inch to 16 feet) per second. By a circuit connection the number of revolutions of the screw is signalled at periods of from 25 to 50, and a simple calculation therefrom determines the relative speed in a moving medium. The process requires the services of two operators and two assistants, lasts from one to two hours, and (including the cost of the electric current) involves an expense of 1*l.* per instrument dealt with.

During the two years 1906–7, surveys have been made of the basins of the Dranses, the Usses, the Fier, the lake of Bourget, the Guiers, the Bourbre, the Gère, the Collières, the Galaure, the Drôme, the Roubion, the Lez, and the Eygues, all tributaries of the Rhone, and comprising an area of 918,643 hectares (2,300,000 acres). These basins are all separately delineated in the volume under review in a series of charts to a scale of 1/200,000, which are accompanied by tables recording various analytical particulars of the component sections, according to superficies and altitude.

A noteworthy feature of several of the smaller basins (especially that of the Collières) is the disappearance and reappearance of streams in and from subterranean passages, resulting oftentimes in several changes of name for a single watercourse, the identity of which can be established without serious difficulty throughout its apparently disconnected track. For example, the same waters feed successively the Reval, the Orou, and the Collières, which thus constitute really a single stream.

An interesting extension of these topographical investigations has been made in reference to some of the principal glaciers, which the commission rightly regard as important reservoirs. The glaciers of Vallouise were surveyed in 1904, those of the Grandes Rousses in 1905, and the glacier of Mont de Lans in 1906–7.

It would be impossible within the limits of a short article to touch upon all the points of interest in M. de la Brosse's report, and the foregoing constitute simply a few random notes culled from pages which are replete with valuable information on all branches of hydrographical research amid the Alps. Mention must, however, be made of two supplementary notes by M. Mougnié, of Moutiers, the first on the subject of controlling the discharges of the Isère, and the second on variations in the bed of the same river. Then follows the second part of the volume, a compendium of more than 600 pages of tabulated data covering the whole area of operations.

The admirable manner in which these observations are being made and recorded reflects the highest credit on the Direction de l'Hydraulique, and abundantly justifies its formation and support. It is evident that there is being collected a wealth of data which must prove of incalculable value in estimating the hydrological resources of the country and in utilising them to the best advantage and to their fullest extent. Further volumes of the series will be awaited with undiminished interest by all who are concerned in any way in the development of hydrotechnical studies.

B. C.

THE SCIENCE OF PATHOLOGY.

The Principles of Pathology. By Prof. J. George Adami, F.R.S. Vol. I., General Pathology. Pp. 948. (London: Henry Frowde and Hodder and Stoughton, 1909.) Price 30*s.* net.

WE congratulate Prof. Adami on the completion of this exhaustive work, of nearly 1000 pages, on general pathology, more particularly as he had the misfortune to lose his library, the manuscript of the concluding chapters, and the illustrations collected over a period of many years for the purposes of the book, in the fire by which the medical buildings of McGill University were destroyed in April, 1907.

The book is divided into three sections, section i. dealing with prolegomena, and in particular with the cell and its relation to disease, section ii. with the causes of disease, and section iii. with the general morbid and reactive processes.

In the opening chapters an excellent summary is presented to the reader of the various theories of cell structure and connections, and of the physiology and chemistry of the cell, including enzymes and their mode of action. In these considerations the author adapts the "side-chain theory" to explain the relationship of the protein molecule to life and metabolism and to enzyme action. Whether correct or no, this conception has the advantage of visualising the subject, and gives the student concrete ideas which he can grasp, in place of abstract ones.

Growth, states of cell activity, cell multiplication, adaptation, and differentiation are next considered, and the important subject of inheritance has, rightly, considerable space devoted to it; and Mendel's and Galton's laws, mutations, and the inheritance of acquired characters all receive adequate treatment.

Having thus cleared the ground by a consideration of these general biological problems, the author passes on to the subject-matter proper, commencing with a discussion of the causes of disease, in which inheritance is again considered, and the various anomalies of development and the monstrosities are very fully described. The bacterial, protozoan, and metazoan parasites are then discussed, but only in a general way, as causes of disease—a wise limitation, as the parasites themselves and their general biology and activities are fully described in various other textbooks. Referring to the presence of bacteria potentially pathogenic in and upon the healthy body, the author mentions that streptococci are present in the mouth in 80 per cent. of healthy people, but it is to be noted that Gordon has shown that the species present in the mouth, and so abundant there, is non-pathogenic, and differs from the disease-producing streptococci.

In the section on malaria it would have been more correct to speak of "anopheline" rather than "anopheles," mosquitoes as agents of transmission.

Chapter xi. is devoted to endogenous intoxications due to abnormalities of internal secretion (*e.g.* of the thyroid, adrenals, pancreas, &c.), which, it is true, gives the essentials of the subject, but fourteen pages seem to us inadequate space in a work of this kind to discuss so important a subject.

In the section on the morbid and reactive processes, the local and systemic reaction to injury and inflammation are dealt with very fully, and altogether in a judicious and instructive manner. Immunity and its various problems are similarly well treated, and a survey is given of every branch of the subject; Ehrlich's "side-chain theory" in particular is well described, and at some length. As regards anaphylaxis—the *increased* susceptibility conferred by an injection of blood-serum—we cannot help thinking that the suggested explanation is laboured, and, involving as it does the ionic hypothesis, beyond our present knowledge of the phenomenon.

The progressive tissue changes—hypertrophy, regeneration, and new growths—are next discussed in a very complete manner. We are glad to note that the author emphasises the futility of attempting to graft the tissues of lower animals on man for purposes of repair.

In speaking of placental moles, the inexact, if not incorrect, appellation "hydatid" is retained; "hydatidiform" is preferable.

The characters of neoplasms (tumours or new-growths) are given at considerable length. The classification of neoplasms adopted is the histogenetic one supported by the author. A principal objection urged by Prof. Adami against the embryogenetic classification is that it separates new growths histologically similar, *e.g.* glioma of epiblastic, and sarcoma of mesoblastic, origin. We venture to think that too much stress should not be laid on this argument, for even now the minuter structure of new growths is only beginning to be studied. Nor are we as yet absolutely certain of the developmental origin of many structures in the body, and further research may clear up some of the apparent discrepancies now incidental to the embryogenetic classification. The histogenetic classification itself is not altogether free from the reproach levelled at the embryogenetic one by Prof. Adami.

As regards the genesis of new growths, the various hypotheses are discussed at considerable length, and an admirable survey of this vexed and complex question is presented to the reader. Prof. Adami considers that no parasitic hypothesis suffices, that Beard's hypothesis of aberrant and misplaced germs and trophoblastic cells (so much in evidence lately in connection with a certain form of treatment) is inadequate, seeks for an explanation in the hypothesis of a change (? a mutation) in the biological properties of the cells giving origin to tumours, and considers that there is no one specific cause; with all these we cordially agree.

The concluding portion of the book deals with the regressive changes, the degenerations and infiltrations, calcification, pigmentation, &c. The book altogether is an inspiring one, and the careful reader will not only gather what is already known, but will be led to infer in what directions further progress lies. A notable feature of it is the attempt made, usually successfully, to ensure a basis on a sound foundation of general biology. It is carefully and adequately illustrated, and the numerous diagrams and schemata serve to render many of the more abstruse conceptions clear and intelligible.

A NEW WAY IN ARITHMETIC.

Theorie der algebraischen Zahlen. By Dr. Kurt Hensel. Erster Band. Pp. xii+350. (Berlin and Leipzig: Teubner, 1908.) Price 14 marks.

IN this volume Dr. Hensel gives the first instalment of a treatise on algebraic numbers, embodying an independent method on which he has been engaged for the last eighteen years. Its leading idea may be illustrated by the following example. Let us take the solvable congruence, $x^2 \equiv 2$ (mod. 7), the roots of which are $x \equiv 3$ and $x \equiv 4$. The same congruence can be solved with respect to the moduli 7^2, 7^3, 7^4, &c., and we obtain the solutions, in least positive residues, (3, 4), (10, 39), (108, 235), (2116, 285), and so on. Taking the first number in each bracket and expressing it in the septenary scale, only writing the digits in the reverse of the usual order, we obtain the associated solutions, 3, 31, 312, 3126; and it is clear that if $x = a_1 a_2 \ldots a_n$ is a solution of $x^2 \equiv 2$ (mod. 7^n), we can find a number $a_1 a_2 \ldots a_n a_{n+1}$, which is a solution of $x^2 \equiv 2$ (mod. 7^{n+1}). There is thus a definite sequence of digits, 3, 1, 2, 6, . . . a_n, . . . such that each is a least positive residue of 7 (or zero), and such that 3126 . . . a_n is a solution of $x^2 \equiv 2$ (mod. 7^n). This sequence may be said to be the symbolical septenary representation of $\sqrt{2}$. But conversely we may take any such sequence, $a_1 a_2 \ldots a_n \ldots$ and define it as a septenary number, in an extended sense. All such numbers form a corpus, provided we introduce septenary fractions of the same type. Since $-1 \equiv (7^n - 1)$ (mod. 7^n), the symbolical form of -1 is 666 . . . or $\dot{6}$; hence every ordinary positive or negative integer or fraction has a symbolic expression which is wholly or partly periodic, *e.g.* $2/3 = (3+\dot{6})/3 = 3\dot{2}$, and so on. Similar results hold for any prime modulus; when the modulus is composite, some curious anomalies occur.

Now let $w_1, w_2, \ldots w_n$ be a basis of an algebraic corpus; we may form symbols of the type $A_1 w_1 + A_2 w_2 + \ldots + A_n w_n$, where $A_1, A_2, \ldots A_n$ are numbers of the kind just described. These new symbols may be called "numbers," and by making use of them Dr. Hensel obtains all the most important known properties of algebraic numbers with surprising facility; he also adds results of his own which are of great interest and beauty. Calling a symbol such as A_1 a p-adic number, we may call $F(x) = A_1 x^n + \ldots + A^n$, a p-adic function; it is shown how to determine, by a finite process, the irreducible p-adic factors of $F(x)$, and by a series of propositions we are led up to the remarkable theorem (p. 159) that if $f(x) = x^\lambda + a_1 x^{\lambda-1} + \ldots + a_\lambda$, the coefficients being integral p-adic numbers, and $f(x)$ irreducible, then if p^δ is the highest power of p which divides the discriminant of $f(x)$, and if α_1 is a root of the ordinary equation

$$\phi(x) = 0$$

obtained from $f(x)$ by omitting all the digits of $a_1, a_2, \ldots a_\lambda$ beyond the $(\delta - 1)$th place, the equation $f(x) = 0$ will have precisely λ conjugate roots $\xi_1, \xi_2, \ldots \xi_\lambda$ expressible as conjugate p-adic numbers in the corpora (α_1), $(\alpha_2) \ldots (\alpha_\lambda)$. This fundamental fact leads to a host of consequences, among them a comparatively simple treatment of a well-known problem, namely, the resolution into their prime ideal factors of the real primes which divide the discriminant of a given corpus. It also leads to a complete theory of congruential roots of unity; the theory of units in a given corpus is not discussed in this volume.

On pp. 308 and following will be found a complete solution of the problem of resolving a given real prime into its ideal factors within a given corpus; this involves the Kronecker method, in which *umbrae* are used, and probably there is no certain practical way which can dispense with them. As an illustration, it is shown that in the corpus defined by the equation $\alpha^3 - \alpha^2 - 2\alpha - 8 = 0$, the number 2 is the product of three ideal primes, which are actually determined.

One of the last theorems proved in this volume may be stated in the following terms:—If a corpus is defined by an equation $f(x) = 0$, which is not Galoisian in the field of ordinary numbers, we cannot make the field Galoisian by the introduction of p-adic numbers.

The value of the treatise can hardly be overrated, and its completion will be anxiously expected. It is interesting to compare it with Hensel and Landsberg's treatise on algebraic functions, and observe the points of contact. A special feature is that in the arithmetical work, like the other, there are expansions in fractional powers; in the algebraic theory it is almost impossible to avoid this, except by tedious divagations, but in the theory of numbers such symbols ought to be avoided if possible, and their occurrence here may cause some readers a shade of regret. G. B. M.

LISSAJOUS'S FIGURES.

Harmonic Vibrations and Vibration Figures. By J. Goold, C. E. Benham, R. Kerr, and Prof. L. R. Wilberforce. Edited by H. C. Newton. (London: Newton and Co., n.d.) Price 6*s.* net.

THE four authors of this book have each contributed an account of the construction and use of apparatus which they have invented or brought to perfection, the several parts of the book being independent of one another, but related by the similarity of the subject-matter. Lissajous's figures were originally introduced as a convenient method of illustrating optically or mechanically acoustic phenomena, but the beauty and perfection of the results obtained by the compound pendulum of Tisley, and later by the twin elliptic pendulum of Goold, have made the subject sufficiently attractive to be pursued for its own sake. As two leading scientific publishers declined to take the book on the ground that it could not pay, we are indebted to Messrs. Newton and Co. for rescuing and producing a book which will be valued in many quarters.

Mr. Benham writes the history of the harmonograph, and describes his own triple pendulum and his own modification of Goold's twin elliptic pendulum. He also gives valuable information to anyone who would construct his apparatus as to the details which are necessary for success. The construction of the ruling pen, choice of inks or dyes, the selection of suitable paper, interesting dodges with photographic plates or with successive chemicals, are a few only of the tips or dodges described. The extremely beautiful stereoscopic effects obtained by viewing two nearly identical harmonograph figures with a stereoscope are described and illustrated, as is the curious change which occurs when such a pair of figures are slowly turned round at the same time, so as to change their relative aspect, the series of lines all appearing on the surface of a cylinder in the one position, and gradually merging into a series, each of which lies between the last one and the axis in the other position. In the case of figures drawn by the twin elliptic pendulum, where it would be next to impossible to draw two successive figures which should be sufficiently alike, the ingenious plan is adopted of selecting those which have a two-fold symmetry, but in which the two halves on opposite sides of the centre are not quite identical, and then simply turning one upside down, in order to obtain stereoscopic shell-like structures of wonderful beauty. Several examples of the marvellous beauty of the twin elliptic pendulum's work are given, in which it is difficult to know whether the forms of the curves or the water-mark patterns are the more to be admired.

Visitors at soirées of the Royal Society will remember the curves drawn by Mr. Goold's big twin elliptic pendulum, as also that queer vibrating and droning steel plate, which gave rise to so many curious phenomena. One passage from Mr. Goold's description may here be quoted.

> "If . . . a small chain be thrown on the vibrating plate, it will immediately settle itself on the curved line between the vortices and . . . will crawl away to the nearest vortex, and there coil itself up like a serpent, continuing to rotate as long as the plate remains sufficiently excited."

This is one only of a number of curious results obtained by Mr. Goold.

Mr. Richard Kerr describes a form of geometric pen, capable of producing very beautiful patterns. This is followed by an account of Mr. Lewis Wright's method of projecting Lissajous's figures on a screen, using reeds in the place of tuning forks, and Prof. Wilberforce describes his well-known sympathetic vibrations obtained by the aid of one or two torsion springs.

This is an excellent book for the Christmas holidays.

C. V. BOYS.

OUR BOOK SHELF.

Cattle of Southern India. By Lieut.-Col. W. D. Gunn. Department of Agriculture, Vol. III., Bulletin No. 60. Pp. 65; plates. (Madras: 1909.) Price 3*s.*

ALTHOUGH the existence of a number of local breeds and sub-breeds of Indian humped cattle (*Bos indicus*) is familiar to Anglo-Indians, comparatively little is known about them in this country, and it is, therefore, highly satisfactory that Col. Gunn, Superintendent of the Indian Civil Veterinary Department at Madras, has furnished us with this elaborately illustrated account of the various types to be met with in southern India. It is, however, a matter for regret that the author did not see his way to make his work complete by including the breeds found in other parts of India. As to the origin of humped cattle, the author is silent, and perhaps wisely so, since, so far as we are aware, nothing definite has hitherto been ascertained with regard to this subject.

If we rightly understand him—and his classification is by no means so clear and unmistakable as it might be—the author considers that there are two main types of large-humped cattle in southern India, namely, the Mysore and the Ongole, or Nellore. The former, which are characterised by the long, more or less upwardly directed, slightly tapering horns, and generally iron-grey or bluish colour, are, however, divisible into a number of sub-breeds, such as the Amrat Mahal, Hallikar, Alumbadi, &c., all of which come under the native designation of Doddadana, or large cattle, in contradistinction to the Nadudana, or ordinary small village cattle. The finest of all are the cattle of the Amrat Mahal breed, which were formerly owned by Tippu Sultan, but became the property of the British Government after the fall of Seringapatam, although the management of the herds remained for a time under the control of the Maharaja of Mysore, on condition of his supplying a specified number of bullocks. In the old days of Indian warfare these cattle were of the greatest value for transport-purposes on account of their rapid pace.

The Nellore, or Ongole, cattle, on the other hand, carry short and somewhat stumpy horns, which are, however, longer in cows than in bulls, and have an outward and slightly backward direction. Formerly black-and-white was in fashion, but white is now the favourite colour for these cattle, the ears of which droop more than in the Mysore type. Although probably less hardy than the Mysore breeds, these cattle are unsurpassed for slow work, a pair, it is stated, being capable of drawing a load of five tons.

The volume closes with a notice of the domesticated buffaloes of southern India, special mention being made of the Toda customs associated with the cult of these animals.

R. L.

Flora of Cornwall. Being an Account of the Flowering Plants and Ferns found in the County of Cornwall, including the Scilly Isles. By F. H. Davey. Pp. lxxxviii+570. (Penryn: F. Chegwidden, 1909.) Price 21*s.* net.

ON account of its extreme situation, the mildness of the climate, and the interesting rock formations, notably round the Lizard, the county of Cornwall exercises a great fascination for students interested in natural history. It is rather strange, therefore, that a county flora should only now be compiled, especially as many botanists—natives, aliens, and others—have found it a profitable hunting ground. Six years ago Mr. Davey published a preliminary list of plants which was deserving of the title of a flora, but this was only intended to form a basis for a more complete survey and to arouse interest in the undertaking; the intention has been entirely successful, and the author's subsequent labours, assisted by energetic and able co-workers, have culminated in the volume under notice, in which the total number of plants is computed at 1180; and of these, 953 are considered to be native.

The greater part of the book is devoted to the enumeration of species, with detailed list of localities for all but very common plants; in this matter the author has been over-bountiful, and space could have been saved by the elimination of the long list of localities for certain species that are in no sense critical, such as *Spiranthes autumnalis* or *Centranthus ruber*. The number of species found in Cornwall, but not recorded for any other county in Britain, amounts to twenty, while a comparison with Devonshire shows that fifty-three plants growing in Cornwall have not been collected in Devonshire, as against 103 confined to the latter county.

A considerable part of the introduction is given up to a history of botanists who have contributed to the county records, and a few photographs of notable local botanists are included; there is also a short account of eight botanical districts which are indicated on an accompanying map, and a list of a few plants peculiar to each, but the author has not attempted an ecological sketch of the chief formations. Among the Cornish botanists the best-known name is that of the Rev. C. A. Johns, the author of "Flowers of the Field" and "A Week at the Lizard," while William Curnow, T. R. Archer Briggs, and Richard Tellam were even more zealous field workers. Mr. Davey, too, has added his quota of records, for which he deserves to rank among the honoured list of local botanists, as also for the strenuous work in connection with this publication. The volume is worthy to rank with the standard county floras, more particularly in the verification of records and critical compilation.

The Elements of Animal Physiology. By Prof. W. A. Osborne. Pp. 152. (Melbourne: Thomas C. Lothian, 1909.)

THE size of this little book will indicate that it contains a mere sketch of the large subject of which it treats. It is written for the purpose of supplying non-medical readers with an introductory account of mammalian physiology, in the hope that they subsequently will take up the question more fully. Prof. Osborne has in Melbourne to teach students of agriculture and veterinary science, in addition to those who are taking full medical or science courses, and it is to the former class of students that the work is specially addressed. One can hardly doubt that agriculturists, especially in Australia, where the breeding of domestic animals forms such a large part of their work, will benefit greatly if they have a rational substratum of physiological facts at their disposal.

The book is trustworthy and free from errors; it is specially full on its biochemical side, which is what one would anticipate from Prof. Osborne's research work. Complex questions, such as those dealing with the nervous system, are treated with extreme brevity, and this is to be regarded as judicious, seeing what class of readers are specially catered for. We wish the book the success it deserves.

A Text-book of Experimental Physiology for Students of Medicine. By Dr. N. H. Alcock and Dr. F. O'B. Ellison. With a preface by Prof. E. H. Starling, F.R.S. Pp. xii+139. (London: J. and A. Churchill, 1909.) Price 5*s.* net.

To some extent this little book is the outcome of a conference of the London teachers of physiology. They have for long felt that a revision of their practical courses was necessary, and the present work, which is issued under the ægis of Prof. Starling, indicates the kind of reform considered desirable. One understands that in the future the practical examinations in the University of London, at any rate, will be largely modelled on the kind of course here presented. The main underlying new idea is that medical students should be taught physiology so as to fit them for being, not expert pure physiologists, but medical men with a knowledge of those portions of the vast subject which will be immediately useful to them in their study and treatment of diseased conditions. The frog is therefore relegated to a position of subsidiary importance, and as many experiments as possible are given in which the mammal, and especially man himself, is the *corpus vile*. It would be ungracious at this stage to point out faults of omission and commission of which the authors, Drs. Alcock and Ellison, have been guilty in their praiseworthy attempt to carry out the new idea. It will only be possible to do so when the book has been tried as a practical guide, and future editions will no doubt, show various improvements, after the present one has been subjected to this test.

W. D. H.

Elementary Photo-micrography. By Walter Bagshaw. Second edition. Pp. 103. (London: Iliffe and Sons, Ltd., 1909.) Price 2*s.* 6*d.* net.

THE object of this little book is to arouse interest in, and give instruction to, those to whom such a study would otherwise possibly appear far too abstruse and full of difficulty. It is most clearly and lucidly written, and there is an evident desire to avoid unnecessary detail. It would be easy to criticise and to point out the many omissions of essential detail that to an advanced worker are only too obvious; but it must be admitted that for the beginner and intelligent worker the instructions would prove, in the majority of cases, ample. Nearly the whole of the course of work suggested may be carried out with simple apparatus: in fact, it is much to the credit of the writer that simplicity, and the absence of any recommendation to use complex apparatus, is the keynote of the entire book. It is perhaps to be regretted that, having gone so far, he has not in some directions slightly extended the work. The instructions in the use of the microscope itself are perhaps unnecessarily meagre, whereas such matter as a list of photographic chemicals required, with the prices—information that can be obtained from any trade catalogue—might easily have been omitted. On the whole, however, the object of the book is fulfilled, and it will form, to those who have a microscope of simple construction, or who, having a camera, wish to apply it for microscopic work as well, a most useful guide. The illustrations are in all cases of a high order, and have been selected, not merely as pictorial examples of photo-micrographic work, but, so far as possible, to bring home to the student the difficulties to be encountered and the results to be attained.

J. E. BARNARD.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Inheritance of Acquired Characters.

IN reviewing Prof. Eigenmann's book on the cave vertebrates of America (NATURE, November 11, p. 40), the reviewer quotes the author's opinion that "The bleached condition of animals living in the dark, an individual environmental adaptation, is transmissible, and finally becomes hereditarily fixed. . . . Natural selection cannot have affected the coloration of the cave forms, for it can be of no consequence whether a cave species is white or black." Your reviewer further dismisses Romanes's supposition that colour may be correlated with other structures which are subject to selection.

Is it not probable that the *mere cessation* of natural selection with regard to colour would produce this colourless condition quite apart from light or other environmental factor?

In the silkworm-moth, *Bombyx mori*, we have a similar absence of colour in both moth and larva, solely, I take it, because no attention has been paid to the colour of either during the many centuries that the species has been *selected for its silk-producing qualities* alone under semi-domestication.

While on this subject, I may perhaps refer to Mr. Wm. Wood Smyth's letter in NATURE of May 6 last (vol. lxxx., No. 2062, p. 277), with reference to the drone breeding habits of some workers of the hive bee affording a possible channel for use inheritance in regard to neuter characters.

I had hoped that this important point would have been the subject of further correspondence by the acknowledged authorities on apiculture.

I thought that this feature of egg-laying workers was, as a rule, confined to queenless hives that were more or less *in extremis*. Presumably the habit would be subject to heredity, and if, as I understand, it is not only a detriment but a source of danger to any community of bees to have any number of egg-laying workers, it seems reasonable to suppose that in wild stocks such a habit would be so stringently restricted by natural selection as to deprive its occasional occurrence in domesticated stocks of any significance in the production of the structural differences or special habits which differentiate workers from queens. It would be of very great interest to know if neuter ants of any species retain the power of laying occasional eggs.

A. BACOT.

MR. BACOT's suggestion with regard to the cessation of natural selection in relation to the bleaching of cave animals has been fully dealt with by Prof. Eigenmann himself in the work under review. It will be only fair to Prof. Eigenmann to quote his own words:—"Panmixia can not account for the discharge of the colour, since it returns in some species when they are exposed to the light and disappears to a certain extent in others when kept in the dark. Panmixia, Romanes thinks, may have *helped* to discharge the colour. In many instances the colour is a protective adaptation, and therefore maintained by selection. Panmixia might in such instances lower the general average to what has been termed the 'birth-mean.' *Proteus* is perhaps such an instance. But in this species the bleached condition has not yet been hereditarily established, and since each individual is independently affected, 'the main cause of change must have been of that direct order which we understand by the term climatic.' Since, however, the bleached condition, which in the first instance is an individual reaction to the absence of light, has become hereditarily established in *Amblyopsis* so that the bleaching goes on even when the young are reared in the light, it is evident that in *Amblyopsis* we have the direct effect of the environment on the individual hereditarily established."

If Mr. Bacot will read the notice again he will see that the reference to "Romanes's supposition that colour may be correlated with other structures which are subject to selection" is a quotation. The reviewer still considers, however, that Prof. Eigenmann has made out a strong case.

ARTHUR DENDY.

Radio-activity and the Rocks.

MR. F. P. MENNELL, in NATURE of November 18, raises the question whether the more strongly active of the rock-forming minerals owe their activity to thorium. I have a considerable number of data on this subject obtained by direct experiment, estimating radium and thorium by their emanations. I find, by this method, that zircon, sphene, and apatite usually contain some thorium, but that it generally contributes less to the activity than the substances of the uranium-radium series.

The Auroral Display of October 18.

THE aurora of October 18 was observed at Allegheny Observatory under conditions somewhat similar to those mentioned by Mr. Ernest Baty in NATURE of October 28 (vol. lxxxi., p. 518). Here, however, the whole sky was dull, hazy, and cloudy at the beginning of the display, gradually clearing toward midnight. No stars whatever could be seen in the region covered by the aurora, which was very bright. This fact might lead us to think that it had its origin in the lower layers of the atmosphere.

The aurora consisted of the usual arch, from which arose streamers at various points, some of them extending to an altitude of about 45°. These drifted westward and gradually diminished in brightness, while they were followed by others in rapid succession. The streamers had at times a reddish tint.

The aurora was still faintly visible at 1 a.m., by which time the sky had become perfectly clear.

Large Flying-fish.

A FLYING-FISH flew on to the lower deck last night about 8.30 p.m. The deck is 20 feet above the water-line, and the railing is 4 feet 6 inches above the deck, but it is possible for it to have flown through the railing; the fish measured 17¼ inches from tip of nose to tip of tail. I forgot to weigh it before it was cooked. It was the largest flying-fish I have ever handled. Could any reader of NATURE kindly inform me what is the largest size known? We were about fifty miles north of Teneriffe when it came on board. The species up here appear to be larger than those in the tropics and near South America. I have seen large ones in the Gulf of Aden, but never caught one, though I am inclined to think this was a larger species. The longest flyers always appear to be the largest fish: the longest flight I have seen has been about 400 yards.

SPINAL ANÆSTHESIA.

The visit of Prof. Thomas Jonnesco, of the University of Bucharest, to the Seamen's Hospital, Greenwich, has brought prominently before the public the method of producing local anæsthesia by the injection of anæsthetic solutions into the spinal canal.

Cocaine was introduced years ago as an anæsthetic for local application; it was welcomed by the medical profession, and equally by patients, on account of its invaluable services in operative procedures upon the eye, the nose and the throat. By merely placing a drop or two of a solution of cocaine (or one of its salts) into the eye, or by painting a similar solution upon the mucous membrane of the nose or throat, it is possible to produce anæsthesia so complete as to enable surgical operations to be performed upon these parts without inflicting the least pain or discomfort upon the patients. Certain objections to the use of cocaine were not long, however, in showing themselves. Cocaine is a powerful alkaloid; and if the usual dose be exceeded, very grave results follow, a number of patients having actually died as the result of cocaine poisoning. Investigators were therefore led to search for other substances, either like cocaine occurring naturally, or prepared synthetically, which would possess the properties of cocaine while being less poisonous.

In this way a number of anæsthetic drugs has been introduced, including alypin, holocaine, eucaine (alpha and beta), scopolamine, novocaine, stovaine and tropacocaine. Of these the three latter have been chiefly employed in producing spinal anæsthesia. The method consists in injecting, by means of a syringe and needle, a quantity (usually about 1 c.c.) of a solution of one of these substances into the spinal canal. The injection is made in the back, close to the middle line, the needle being inserted between two of the vertebræ. With regard to the details of the method, various procedures have been described, and no agreement has yet been reached as to which of these is to be considered the best. There is no doubt that modifications are desirable to suit particular requirements. Thus, many operators direct that the drug be dissolved in cerebro-spinal fluid or else in a saline solution having the same specific gravity and the same osmotic tension as the blood-serum. Others consider that the anæsthetic solution should be considerably denser or more viscous than the cerebro-spinal fluid, and for this purpose recommend the addition of glucose or of gum-acacia to the solution. These thicker solutions tend to remain at the spot at which they are injected, while solutions in cerebro-spinal fluid or in normal saline tend to spread up and down the spinal canal, and thus have a more widespread anæsthetic effect. It is usual to withdraw a few c.cm. of cerebro-spinal fluid from the spinal canal before injecting the anæsthetic fluid. There are two reasons for this—first, the surgeon is assured that he has actually introduced his needle into the spinal canal, and secondly he is certain to avoid increasing unduly the cerebro-spinal pressure when he introduces the anæsthetising fluid.

On introducing the fluid into a particular part of the spinal column, anæsthesia is produced of all parts of the body deriving their nerve supply from this part of the spinal cord, and all parts below. If the fluid be allowed to ascend the spinal canal (*e.g.* by raising the hips) the anæsthesia rises higher and higher as the anæsthetic fluid reaches the trunks of the nerves arising from the higher parts of the spinal cord. If the patient be placed on one side while the injection is being performed, the anæsthetic fluid can be made to enter one lateral half of the spinal canal, and in this way it is possible to limit the anæsthesia to one lateral half of the body.

The anæsthetic fluid can be allowed to ascend almost to the top of the thoracic spine without fear of untoward consequences. When it reaches the base of the neck, however, the phrenic nerve, concerned with the movements of respiration, becomes involved, and it was deemed impracticable to produce anæsthesia of the head and neck by the spinal method. Prof. Jonnesco, however, has shown that the addition of strychnine to the anæsthetic solution produces so powerful a stimulant effect upon the respiratory centre in the brain that it is possible to introduce an anæsthetic fluid into the upper part of the thoracic spine, and to allow the fluid to ascend the spinal canal in the neck so as to enable operations to be performed upon the neck and throat. But it is as yet too early to say whether this method may be considered a safe one.

Of the three drugs which are now chiefly used for the production of spinal anæsthesia, stovaine is found to produce the most deleterious effect upon the kidneys, acute nephritis having followed its injection in quite a number of cases. Novocaine and tropacocaine are less injurious in this way, while they are equally efficacious as anæsthetics. It thus appears likely that they will supplant stovaine in the near future, and, in fact, tropacocaine in a one per cent. solution is already being largely used for the purpose in this country, the usual dose injected being about $1\frac{1}{4}$ grain.

No doubt further experience will lead to modifications in the present method of performing spinal anæsthesia which will result in its widespread use, as there are a great many cases in which a local anæsthetic is far more advantageous to both patient and surgeon than a general anæsthetic.

A. C. J.

THE CAUSES OF THE GERMINATIVE PROCESSES OF SEEDS.

One of the most remarkable phenomena of vegetable life is the occurrence in its cycle of a resting period of varying duration, a period during which the vital functions seem entirely suspended or dormant, and the condition of the organism is hardly distinguishable from death. This stage is most common in connection with the reproductive processes, and can be seen to belong to the constitution of both spores and seeds. The more highly differentiated the structure which shows it, the more prolonged, apparently, can be this resting period, but sooner or later it gives place to the resumption of growth and vital activities.

The interpretation of the occurrence of this phase is rather a matter of inference than proof; probably it was originally concerned in the protection of the reproductive structure from adverse conditions of the environment, for not only is the life rendered dormant, but the resting organ is for the most part protected by modification of its tegumentary covering. In this condition it is able also to bear the severance of its organic connection with its parent, and to subserve the purposes of dispersal. It may, indeed, have arisen with special reference to the latter process alone.

The resumption of the growth and development of the reproductive body after the period of rest may be explained in a similar manner by the reversal of the adverse conditions, these being for the most part secured when its dispersal has been effected.

These superficial considerations are found, however, on reflection, to have others underlying them. Is the resting period of any advantage to the living substance of the reproductive structure, whether spore or seed? Does the cessation of the vital activity afford it any increased power of growth or vigour of constitution? Is it only a condition induced by circumstances, or does it speak of a rhythmic tendency inherent in the plant?

More interesting still—Is the resumption of life which we call germination an evidence of the attainment of such increased vigour, or is it merely the resumption of ordinary chemical change when inhibiting conditions are removed? In the latter case, is the living substance concerned in setting up such chemical changes, or do these arise without such initiation?

If we study the germinative changes we find them associated universally with the existence and activity of enzymes. The resting germ, whether the structure be seed or spore, is surrounded by food material deposited for its ultimate nutrition, but needing enzymic action to render it suitable for actual assimilation. The number of such enzymes known to physiologists has increased most remarkably during the last decade, and though they have been found to be most plentiful in seeds, the study of the spore has shown that it is similarly equipped, though from its unicellular character the distribution of the enzymes is much simpler. At a certain moment the germ starts into life, simultaneously the enzymes are found at work, and nutritive pabulum is presented to it in assimilable form. Which is cause and which effect? Does the living substance, awaking from a sleep, start the enzymic activity, or do the enzymes originate the change? Is the activity of the living substance itself due to enzyme action? In other words, is life a question of the existence and activity of enzymes?

These subjects can be studied more advantageously in a seed than in a spore on account of the physiological as well as anatomical differentiation which it presents. It is easy to distinguish the germ which, after resumption of growth, becomes the new plant, and to separate it from the stores of food which are laid up for its nutrition, and which will be the sphere of activity of the digestive enzymes. These stores may be within it or lying around it, but they in any case are well away from its actual growing points. In such a seed, then, we can distinguish the germ, or embryo, the new plant, and the remains of the parent which has given it origin, this being sometimes large, sometimes small, in proportion to the former.

At the outset we may ask, what is the actual condition of these two parts? How far can we find evidence of life in either during the period that elapses between the severance from the parent plant and the resumption of growth and activity after the resting stage? If we study the phenomena of life in the seed as a whole, we are led to apply to it the test of the existence and maintenance of respiration, this being the inseparable accompaniment of metabolic change and hence a constant feature of life in the various conditions with which we are acquainted. If we rely on either the absorption of oxygen or the exhalation of carbon dioxide, however, we shall be obliged to deny the presence of life in the seed at all. Many and careful examinations have been made of the respiratory processes in seeds of many descriptions. Perhaps the most exhaustive of them were those of Romanes in 1893. Seeds of various plants were kept in glass tubes which had been exhausted so completely that they contained only one-millionth of an atmosphere, and were left for upwards of a year. This treatment did not hinder their subsequent germination. Some of them were afterwards immersed in various inert gases, such as hydrogen and nitrogen, others placed in carbon monoxide, sulphuretted hydrogen, vapours of ether and chloroform, and kept thus for twelve months, still without any deleterious effects. It seems hard to suppose them living in the usual acceptation of the term. In 1892 Jodin imprisoned some seeds in ordinary air in hermetically sealed flasks; he kept them so for four years, and examination of the air at the conclusion of this term showed its composition absolutely unchanged, no exhalation of carbon dioxide having taken place. Respiration, as ordinarily understood, thus seems to be quite in abeyance.

The suspension, if not disappearance, of life during this resting period is emphasised by the behaviour of the seeds under exposure to extremes of temperature. Observations made by Wartmann so long ago as 1860 showed that germination was not prevented by preliminary exposure of the seeds to temperatures ranging from −40° to −78° C. This does not seem, however, to prove the point, for the normal temperature of agricultural land in Siberia in winter is almost as low, often reaching −60° C. Experiments were made by de Candolle and Pictet in 1879 which carried the range of temperature a little further, but the most drastic treatment was rendered possible by the liquefaction of air. Experiments with the aid of this powerful reagent have been made in France by Pictet, and in England by Brown and Escombe and by Sir W. Thiselton-Dyer, with the result that such extreme cold had very little effect in inhibiting the power of subsequent germination.

At the other end of the thermometric scale strange results have been found, many seeds having been proved capable of germinating after being exposed for a short time to temperatures higher than the boiling point of water. So long ago as 1877, Just heated seeds of a species of Trifolium to 120° C. without injuring their power of development. Some years later a more extended series of experiments was carried out by Dixon on seeds selected from several natural orders, all of which withstood, without injury, a temperature of about 105° C. prolonged for several hours. Their vitality and power of development were, however, much more easily affected by heat than by cold.

This resistance to great extremes of temperature has been found to be correlated in a considerable degree with the state of desiccation which was characteristic of the seeds. Hence is lent some support to the view of the dependence of germination on enzymic action, for the latter can only be exercised in the presence of water. Some experiments carried out by Acton in 1893 seem to show that even the small amount of water in the wheat grain enables a certain amount of digestive change to take place in both the proteins and the carbohydrates of the grain. In the absence of all moisture the enzymes remain quiescent.

As it is generally accepted that chemical action cannot take place at temperatures so low as those specified, and as chemical change or metabolic activity is an inevitable accompaniment of life as defined by Herbert Spencer, the idea that germination is dependent upon the continued and permanent life of the protoplasm in the resting seed, there have been many efforts made to explain these anomalous manifestations. C. de Candolle concluded that after a certain time the protoplasm of the ripe seed passes into a state of complete inertness, in which it is incapable of either respiration or assimilation, and that while in this condition it can support, without detriment to its subsequent revival, rapid and considerable lowering of temperature. Indeed, the access of cold to a seed seems to be only injurious as it can bring about the freezing of the water remaining in it, with the subsequent thawing as the temperature rises again. This freezing once brought about, further and more intense cold has no effect. Brown and Escombe endorsed de Candolle's idea, suggesting that protoplasm may exist in two conditions, the *static* and the *kinetic* in the former becoming so stable as to be absolutely inert, devoid of any trace of metabolic activity, and yet conserving the potentiality of life.

It is extremely difficult to decide which of the two theories provides the most satisfactory explanation of the observed phenomena. The conditions which mark the commencement of germination help us, however, to come to a conclusion, though difficulties are met with in either hypothesis. For germination to occur, moisture must be absorbed by the seed; absorption of oxygen and exhalation of carbon dioxide speedily follow, enzymic action supervenes, and the digestive changes in the reserve food materials can be readily traced. But what is the first result of the absorption of water is not so clear; is it the resumption of the kinetic condition by the protoplasm, the life of which in all other parts can be seen to be dependent on water, or is it the setting up of the activity of the enzymes, which enables metabolic, and possibly respiratory, changes to take place, such chemical action stimulating the latent life to manifestation?

Certain observations tend to show that the activity commences with changes in the embryo or germ. Van Tieghem, many years ago, endeavoured to excite into activity the endosperm of the castor-oil bean after removing from it every particle of the embryo. In most cases he failed, but in some he claimed to have been successful. The writer, many years afterwards, repeated his experiments, and found that the endosperm could only be quickened when a small portion of the germ was left in contact with it. The changes in this case originated in the embryo. Further observations showed that the earliest sign of germination in the latter is a change in certain cells of its epidermis, which take on the appearances that usually indicate the conversion of a zymogen into an enzyme. The germ appears to start the change by the secretion of an enzyme. It seems justifiable to associate this secretion with the re-assumption of life by the embryo, because, though many enzymes occur in the seed outside the latter, they do not initiate their changes until later. In this particular seed, vital activity is subsequently soon manifested in the tissue of the endosperm, which becomes the scene of very active chemical change, its residual protoplasm growing and secreting certain constituents, particularly sugars, which the resting cells do not contain.

Brown and Morris showed that a somewhat similar procedure can be observed in the barley grain. The first visible changes are the secretion of enzymes by the scutellum of the germ. The germination once started, other enzymes make their appearance in the endosperm, some arising especially from the aleurone layer underlying the testa.

A scrutiny of the results of Dixon's experiments on heating the resting seeds points also to the protoplasm as the initiator of the changes. Exposure of his seeds to 105° C. must have destroyed any preformed enzymes unless the cells were absolutely devoid of water, a condition hardly likely to be reached. The germinative power fell gradually, or nearly regularly, as the heating was raised to this point, but much remained. When, however, a very slightly higher temperature was reached, about 107° C., the seeds lost it with great suddenness and very irregularly. The injury inflicted by the last two degrees was very different from that which was sustained as the temperature gradually rose to 105° C., and was hardly explicable on the theory of enzyme destruction. It did not, at any rate, correspond to the progress of their destruction in the laboratory.

Some experiments recently carried out by Miss White in Prof. Ewart's laboratory at Melbourne bear upon this aspect of the problem. She endeavoured to accelerate the germinative processes in seeds which had but little power of germination by supplying them with additional quantities of enzymes dissolved in the water with which they were kept moist, the coats of the seeds being perforated here and there to allow absorption to take place. Though she examined many in various conditions, the result was always negative. It proved impossible to accelerate germination by supplying additional quantities of enzyme.

Experiments made by supplying resting seeds with reagents such as dilute organic acids, which stimulate their secretion of enzymes, also have been found to be without result.

The idea that enzymes initiate and maintain the process of germination appears, therefore, to be erroneous, and the older view of the sufficiency of the idioplasm of the cells still holds the field, in spite of the difficulties that have been raised by the experiments with temperature. The theory of static and kinetic states of protoplasm explains little or nothing; it is really scarcely more than a statement of the problem in new terms.

J. Reynolds Green.

DR. W. J. RUSSELL, F.R.S.

William James Russell was born in May, 1830, at Gloucester, where his father was a banker. He was educated at private schools—Dr. Wreford's at Bristol, and afterwards at Mr. Bache's at Birmingham. In passing, it may be noted that this was before the educational revival that produced and was furthered by the Public Schools Commission of 1859, and that in those days there were very many private schools where scholarship was carried to quite as high a level, and when the conditions of out-of-school life were in some respects much better than in most of the public schools of the time.

After leaving school in 1847, Russell entered University College, London, where he studied chemistry under Thomas Graham and Williamson. In 1851 he was appointed the first demonstrator of chemistry under Frankland in the then newly-founded Owens College, and helped to plan and superintend the building of the first chemical laboratory of the college. This laboratory, built on what had been the garden attached to the original college building (Mr. Cobden's old house in Quay Street), was the cradle of the great Manchester School of Chemistry, which has become as famous in its way as the Manchester School of Politics. After two years at Owens College, Russell went to Heidelberg, where he worked under Bunsen from the autumn of 1853 to the end of the session 1854–5. During his stay at Heidelberg, he graduated as Ph.D. After his return to England, he lectured at the Midland Institute, Birmingham, and near the end of 1857 came again to London to act as assistant to Williamson, his former teacher, at University College. He was associated with Williamson for several years, a considerable part of the time being occupied with working out and bringing to a convenient practical form a method of gas-analysis whereby the corrections involved in taking account of variation of pressure and temperature were in great measure eliminated. The results of this investigation were embodied in several papers published in the Journal of the Chemical Society and elsewhere, and the form of apparatus finally arrived at was the forerunner of the most improved modern types of gas-analysis apparatus and instruments for the application of the measurements of gases to quantitative analysis.

From 1868 to 1870, Dr. Russell was lecturer on chemistry in the Medical School of St. Mary's Hospital. In the latter year he was appointed to a similar office at St. Bartholomew's and retained this appointment until 1897. After his retirement, he continued his experimental work, and until very recently was actively occupied at the Davy-Faraday Laboratory. He died at his house at Ringwood, after a very short illness, on the twelfth of the present month (November, 1909).

At the time of his death, Dr. Russell was one of the oldest Fellows of the Chemical Society, having been elected in 1851. He served on the council from 1863 to 1867, and from 1870 onwards his official connection with the society was unbroken: he was a member of the council from 1870 to 1872; vice-president, 1872 to 1873; secretary, 1873 to 1875; treasurer, 1875 to 1889; president, 1889 to 1891, and since the last date a permanent vice-president. The society, which was only ten years old when Russell joined it, celebrated the jubilee of its foundation in 1891, during his term of office as president. It naturally devolved upon him to take the leading part in the proceedings, and all who were present must have been struck by the admirable manner in which he acquitted himself. He had to make many speeches, long or short, and they were always simple and appropriate. Without wasting words, or any apparent striving after effect, he managed every time to say exactly what wanted saying.

He was elected a Fellow of the Royal Society in 1872; he served twice on the council, and was a vice-president from 1897 to 1899. He was an original member of the Institute of Chemistry, founded in 1877, was president from 1894 to 1897, and served various other offices between 1878 and 1904.

Dr. Russell's connection with Bedford College (London) extended over many years of his life, and was of very great value to the college. It began with his being appointed professor of natural philosophy in 1860. He retained this office until 1870, and opened in 1860 the first laboratory accessible to women-students for practical work at science. He was a member of the council of the college from 1878 to 1903, being chairman from 1887, and also chairman of the college board of education from 1895. During Dr. Russell's chairmanship, the college was twice enlarged, and at the end of his term of office the necessity for still further extension had become so pressing that it was decided to start a fund to provide an entirely new building. He was an active supporter of this movement, and contributed liberally to the fund.

Dr. Russell's contributions to the methods of gas-analysis have been mentioned already. Among other investigations, we may refer to those relating to the atomic weights of nickel and cobalt (1863 and 1869), which were important in consequence of the way in which results obtained by very different methods were employed to check each other; a series of papers in conjunction with Dr. Samuel West, F.R.S., on a new method of estimating urea, which gave rise to a valuable clinical method; papers (conjointly with Mr. Lapraik) on absorption spectra, and notably one on the absorption bands in the visible spectra of colourless liquids, which was the pioneer paper in a branch of inquiry that has been most ably followed up by Prof. Noel Hartley, F.R.S., Mr. E. C. C. Baly, F.R.S., and others; a remarkable series of papers on the action of metals, resins, wood and other materials on a photographic plate in the dark. Some of the results of this investigation were given to the Royal Society as the Bakerian lecture for 1898. By well-directed and persevering experiments, the effects observed were traced to the generation of peroxide of hydrogen. In another set of experiments on the figures formed by the deposition of dust, Dr. Russell demonstrated the curiously definite course of the convection currents of air that rise from a heated solid body.

A report made to the Science and Art Department, in conjunction with Sir William Abney, on the action of light on water-colours was published as a Blue Book in 1888. It involved a very careful investigation of the subject, and was highly appreciated by artists. A committee consisting of the president and other prominent members of the Royal Academy in reporting on it said that they "unanimously desired to record their sense of the very great value and of the thoroughness and ability with which so laborious an inquiry had been conducted."

In manner, Russell was quiet and entirely free from anything approaching self-advertisement, but he was genial and hearty with his friends, and was gifted with a sympathetic laugh that it was always refreshing to hear. As some indication, both qualitative and quantitative, of the estimate formed of him by his fellows, it may not be out of place to mention that, as a young man, he was the first secretary, treasurer, and keeper of the archives of the B Club—originally a society of young chemists which grew out of Section B of the British Association, first took definite shape at the Oxford meeting in 1860, and kept itself alive between the meetings of the Association by consuming monthly beef-steak puddings at the "Cheshire Cheese"—and that, in later life, he was elected to serve on the committee of the Athenæum Club. His death will be felt as a sore personal loss by very many. He was liked by all who knew him, and by all who knew him intimately he was held in affectionate esteem.

Dr. Russell married, in 1862, Fanny, daughter of the late A. Follett Osler, F.R.S., of Edgbaston. He leaves one son, and a daughter married to Dr. Alexander Scott, F.R.S. G. C. F.

NOTES.

THE *Standard* for November 22 contains a full list of the House of Lords, classified according to their qualifications. It is disappointing to find only two names—those of Baron Rayleigh and Baron Lister—under the heading "Scientists," while "Educationists" are only represented by Baron Ashcombe, member of council of Selwyn College; Baron Killanin, member of Senate of Royal University of Ireland; and the Earl of Stamford, formerly professor of classics and philosophy at Codrington College, Barbados. There are thirty-five railway directors, thirty-five bankers, and thirty-nine so-called "captains of industry" on the list, and a column and a half under "Military and Naval Services."

AT the meeting of the Royal Society of Edinburgh on Monday, November 22, the Makdougall-Brisbane prize for the biennial period 1906–8 was presented to Mr. D. T. Gwynne-Vaughan for his papers (1) "On the Fossil Osmundaceæ," and (2) "On the Origin of the Adaxially Curved Leaf-trace in the Filicales"; and the Gunning Victoria Jubilee prize for the third quadrennial period 1904–8 was presented to Prof. G. Chrystal, for "A Series of Papers on 'Seiches,' including 'The Hydrodynamical Theory and Experimental Investigations of the Seiche Phenomena of Certain Scottish Lakes.'"

THE Livingstone gold medal of the Royal Scottish Geographical Society has been presented to Sir Ernest Shackleton, in recognition of his work in the Antarctic.

PROF. W. BATESON, F.R.S., professor of biology in the University of Cambridge, has been appointed director of the John Innes Horticultural Institution at Merton, Surrey.

LIEUT.-COLONEL D. PRAIN, F.R.S., director of the Royal Botanic Gardens, Kew, and Prof. F. O. Bower, F.R.S., regius professor of botany in the University of Glasgow, have been elected corresponding members of the Munich Academy of Sciences.

THE council of the Royal Meteorological Society has awarded the Symons gold medal to Dr. W. N. Shaw, F.R.S., in recognition of the valuable work which he has done in connection with meteorological science. The medal will be presented at the annual general meeting of the society on January 20, 1910.

THE King has approved of the Polar medal, with a clasp, inscribed "Antarctic, 1907–1909," being granted to members of the Shackleton Antarctic Expedition, 1907–9, the clasp alone being awarded to those who already possess the Polar medal; the medal and clasp to be in silver for the shore party and in bronze for those who remained with the ship.

DR. T. G. LONGSTAFF writes to the *Times* from Kashmir to correct a statement made in the issue of October 1, and referred to in NATURE of October 7, to the effect that he had found that the source of the Tarim River of Kashgaria is in the Siachen Glacier of Nubra. He says that what he has just been able to prove is that the Siachen Glacier of Nubra is merely the lower portion of the glacier found beyond the Saltoro Pass by Dr. A. Neve, Lieut. Slingsby, and himself in June last, and temporarily designated the Terim Glacier.

A MEETING of subscribers, both ladies and gentlemen, will be held at 5 p.m. on Tuesday, November 30, at the rooms of the Society of Antiquaries, Burlington House, London, to determine in what manner the fund which has been raised as a memorial to the late Prof. Arthur Gamgee should be applied to serve the object for which it was collected. Subscriptions may be sent to Prof. Arthur Schuster, Victoria Park, Manchester; Dr. A. D. Waller, Physiological Laboratory, University of London, S.W.; or Dr. G. A. Buckmaster, University College, London, W.C.

THE annual meeting of the Iron and Steel Institute will be held on Wednesday and Thursday, May 4 and 5, 1910. The proceedings will begin by the induction of the new president, the Duke of Devonshire, into the presidential chair by the retiring president, Sir Hugh Bell, Bart. Under the new bye-laws the council now has the power to elect honorary vice-presidents from among distinguished members of the institute who, by reason of their residence out of Great Britain, are unable to take a very active part in the affairs of the institute. The council has accordingly elected the following to the office of honorary vice-president:—Mr. John Fritz, United States; Mr. William Kestranek, Austria; Baron Fernand d'Huart, France; Mr. F. W. Lürmann, Germany; and Mr. E. J. Ljungberg, Sweden.

THE summary of the weather for the week ending November 20, issued by the Meteorological Office, shows that the conditions for the period were generally dry and fine over the entire kingdom. The temperature was everywhere below the average, the deficiency amounting to 11·6° in the west and east of Scotland, 9·6° in the north of Scotland, and 8·7° in the north-west of England. The minima, which occurred in most places about the middle of the week, were extremely low in Ireland and Scotland, making a record for November in parts. At Balmoral the sheltered thermometer on November 16 fell to 3°. The radiation temperature on the grass fell to −5° at Crathes, in the east of Scotland, to zero at Balmoral, and to 8° at Markree Castle. At Greenwich frost occurred only on one night in the shade during the period, but in the open, on the grass, there was a frost each night. The rainfall was less than the average in all parts of the kingdom, and in many parts the week was rainless.

ON November 18 and succeeding days the famous volcanic mountain Pico de Teyde, on the north-west of the island of Teneriffe, was in eruption from four craters lying from east to west. The two inside craters are reported to be active alternately, emitting liquid lava only. Owing to the configuration of the ground it is not possible to dam the lava streams or to divert them into channels where they would do less damage. On November 21 the lava stream is said to have travelled $3\frac{3}{4}$ miles since the beginning of the eruption. An official telegram from Teneriffe on November 23 reports:—"The chief crater continues to throw out large quantities of incandescent matter to a height of above 2000 feet. The flow of lava is increasing in volume. The stream running down the Santiago Valley has divided into two, each 12 feet deep and of constantly increasing breadth. The stream flowing in the direction of the Tauranno is advancing more rapidly, and will shortly be swollen by its junction with another stream which has branched off from the main flow. The lowest point of the stream flowing towards Tanque has made no progress since yesterday, and there appears for the moment to be no fear of its resuming its advance, as the crater by which it is fed is becoming less active. On the other hand, the activity of the craters from which the lava flows towards the Santiago Valley is increasing."

THE board of anthropological studies of the University of Cambridge recently re-appointed Mr. A. R. Brown, of Trinity College, to the Anthony Wilkin studentship. This studentship was founded in 1905 in memory of Anthony Wilkin, of King's College, Cambridge, by his parents, for the encouragement of research in ethnology and archæology. Mr. Brown was elected to the first studentship in the same year, having intimated his desire of studying the social structure and religion of the Andaman Islanders. He returned about eighteen months ago, and since that time has been occupied in writing up his field notes. It is expected that his monograph on the Andaman Islanders will be published next spring. Dr. A. C. Haddon informs us that Mr. Brown's next expedition will be to Western Australia. Extremely little is known about the ethnology of the whole western portion of Australia, and as Westralia is being rapidly developed it is essential that the natives should be thoroughly studied before it is too late. From what little is known, it is evident that the social system of the natives is not uniform, and it is to be hoped that the transition from one form of social organisation to another may be discovered. Mr. Brown proposes to make a general survey of the social and religious conditions of as many tribes as possible, and to make a minute study of one or two of them. If funds permit, he will traverse the continent so as to link up his observations with those of other ethnologists, and at the same time he may be able to clear up some disputed points in the results obtained by previous workers in the field.

THE eighth exhibition of motor-cars arranged by the ociety of Motor Manufacturers and Traders was held at Olympia during last week. The principal point regarding the many cars exhibited is the almost entire absence of chain drive; in almost every case the live axle is adopted.

In several cases the gear-box is secured rigidly to the engine, thus securing correct alignment should warping of the frame of the car occur. Many of the cars are fitted with front-wheel brakes; the Allen-Liversidge arrangement consists of band brakes on drums secured to the steering wheels on the steering bracket sides, and operated by means of cables passing over pulleys mounted on the steering pivots. The risk of side-slip is much reduced by having the brakes on the front wheels. Most of the cars are petrol driven, steam and electric cars being represented by a few examples only. Among the many accessories shown, the Bowden speed indicator is worthy of notice. In this indicator five steel balls move in radial slots in a rotating disc, and as the speed increases they move outwards and also upwards, being guided by a cup-shaped disc, on which they rest. Another disc, resting on the top of the balls, thus has an upward movement communicated to it, and actuates a pointer through a rack and pinion gearing. The indicator has great sensitiveness and freedom from lag, and, owing to the absence of revolving links, springs, &c., should be applicable to the indicating of much higher speeds of rotation than most instruments at present available are capable of dealing with.

THE subject of the prehistoric antiquities of Scandinavia continues to receive attention in *Naturen*, Prof. A. W. Brøgger contributing an article to the November number in which objects of this nature are figured. Attention is directed to the light thrown on Scandinavian antiquities by those of other countries. Among the figures are copies of two excellent prehistoric representations of reindeer and another of a bear.

THE progress of the plan for marking young birds in this country, initiated by the editors of *Witherby's British Birds*, forms the subject of a note in the November issue of that serial. Out of 4750 rings issued, only 2200 are reported as having been used, this comparatively small proportion being largely due to the late date on which the distribution was made. Taking this fact into consideration, the originators of the scheme consider that the number of birds ringed is satisfactory, and lend to expectation of interesting results, which it is hoped will be exceeded next year, when the rings will be issued sooner.

IN the report of the Museums of the Brooklyn Institute of Arts and Sciences for 1908, Dr. F. A. Lucas is enabled to record a marked improvement in the exhibition series owing to the completion of the east wing of the main building. Great stress is laid on the importance of displaying the exhibits in a picturesque and attractive manner, which can be done, if proper care be exercised, without in any way impairing their scientific interest. It is intended to add pictures of invertebrate life above the cases devoted to the lower organisms, and a beginning has been made in the shape of a sketch of a coral-reef. Other paintings are to be devoted to the beach of a coral-island, the purple jelly-fish, and the Portuguese man-of-war. Attention is directed to a recently mounted group of hoatzias, of which a photograph forms the frontispiece to the report.

IN the September number of the Biological Bulletin of the Woods Hole Laboratory Prof. Raymond Pearl and Miss M. R. Curtis give an account of a partially hermaphrodite Plymouth rock fowl hatched at the Maine Agricultural Station in the spring of 1907, and killed in August, 1908. As regards colour and bodily shape, this bird resembled a normal female of the breed, but the head and neck, especially in respect of the development of the comb and wattle, recalled a young cock. In general behaviour it resembled a hen rather than a cock, although it occasionally made unsuccessful attempts to crow. Internally a large lobulated gland on the left side occupied the position of the normal ovary, while there was also a complete and functional oviduct; but on the opposite side occurred a small organ representing a testicle, with a normal efferent duct leading to the cloaca. The sexual glands of each type were in a degenerate condition, and apparently incapable of developing their proper sexual elements. The authors of the paper cite another instance of incomplete hermaphroditism in domesticated fowls, as well as one in which the hermaphroditic character was fully developed.

AFTER describing certain new forms of the remarkable fossils typified by those named Edestus, Prof. O. P. Hay, in No. 1699 (vol. xxxvii., pp. 43–61) of the Proceedings of the U.S. National Museum, discusses the nature of these spiral serrated structures. It has been generally considered that these structures represent the spines found on the tails of rays like Trygon. Dr. Hay is, however, of opinion that they should be associated with the dorsal fin. Their structure may be most easily explained "by supposing that some ancient elasmobranchs developed in front of a median dorsal fin, or in place of it, not a single spine, but a succession of them. The new compressed spine, serrated in front and behind, arose in front of the older ones. Nevertheless, the root of the new spine became directed backward beneath and on each side of the preceding one, so as partly to embrace it. At first probably the older spines were shed, but in time they began to cohere and thus form a compound spine. In Edestus this was straight or slightly bent. All, or nearly all, of it, except the serrated teeth, was buried in the flesh. As more and more elements were added, the organ became more curved, and finally in some species formed a spiral, which was directed backward and the last turn of the shaft of which was elevated enough to keep the teeth from cutting into the skin. Such a weapon could be brought into action if only its possessor had dived under its victim and brought the spine across its abdomen, thus disembowelling it. . . . It is in this way that Gasterosteus attacks its victims."

THE abnormality known as vivipary, in which young shoots are formed in place of flowers, is described by Mr. G. N. Collins in Contributions from the United States National Herbarium (vol. xii., part x.) for some varieties of the maize plant imported from Mexico and Central America into the States. The shoots arise in the axil of a glume in the position of staminate spikelets, and roots are developed at the base; plantlets placed in the ground made some growth, but failed to mature. The phenomenon is attributed to the excessive vegetative growth shown by tropical varieties of corn when transported to a temperate region. The title-page and index to the volume have now been issued.

AN account of the pear thrips, *Euthrips pyri*, prepared by Mr. D. Moulton, and published by the United States Department of Agriculture as Bulletin No. 68, part i., of the Bureau of Entomology, is the outcome of the writer's investigation of a pest which flourished for two years in the San Francisco region. There is an instructive comparison of the light ravages on the early flowering almond, with the destruction caused on the later blooming prunes, cherries, and pears, that open their flower buds just as the thrips reach their active feeding stage. During the second larval stage the insect enters the ground, where it pupates, and finally emerges as an adult thrip in the spring.

The underground hibernation provides an opportunity for killing the larvæ by ploughing; also the insect has various natural enemies in the shape of spiders, mites, and an unidentified fungus.

An article on *Cornus macrophylla* and other species of the genus is communicated by Mr. B. Hemsley to the *Kew Bulletin* (No. 8). He points out that two evidently different species are passing under the name of *Cornus macrophylla*, the one with opposite leaves, correctly named, the other with alternate leaves, for which he proposes the name *Cornus controversa*. He also describes three new Asiatic species, and discusses the nomenclature of some recent determinations. A short note that deserves mention, partly with the view of eliciting more information, refers to the reported use of plant extracts in Siam as remedies for snake-bite. The evidence depends upon the testimony of natives, who supplied specimens of the plants, which have been identified as *Barleria lupulina* and *Justicia Gendarussa*, both members of the Acanthaceæ. The extract gave characteristic alkaloidal reactions, and contained a quantity of calcium and potassium; these properties are possessed by several plants of this family.

The Journal, formerly called the Bulletin, of the Tokyo College of Agriculture, recently received, contains several papers on the availability of various phosphatic manures and on the influence on crop-yields of different ratios of lime to magnesia in the soil, a subject to which considerable attention has been paid in Japan. One of the most striking results obtained was that the manurial value of lecithin is about equal to that of sodium phosphate, whilst phytin is nearly equivalent to ferric or aluminium phosphate; nuclein possesses very little manurial value. The experiments were made in soil culture, but similar results are said to be obtained in sand culture also. Of these three compounds, phytin occurs most commonly in plants, and the other two in much smaller quantities. The experiments were devised to throw light on the changes taking place when vegetable matter is dug into the ground, and to explain the beneficial effect on the succeeding crop.

The Department of Agriculture, Madras, has issued a bulletin describing improvements in paddy cultivation on a farm under the management of the Court of Wards. The best and cheapest fertiliser was found to be farmyard manure, but a sufficient quantity is not available, and recourse is therefore had to other fertilising materials. Certain plant residues, leaves, poonacs, &c., may be used, but they are too expensive if they have to be brought from any distance. The most successful plan has been to cultivate leguminous crops on the wet land itself during the dry season and in the season in which there are only occasional showers of rain, then to pull up and trample in the crop after ploughing the land.

The Bulletin of Agricultural Information of the Department of Agriculture, Trinidad, contains numerous notes on cacao. The maintenance of the fertility of the soil is likely to become an important problem before long; at present it is not unusual for a few acres of land to be rented, and when they cease to be remunerative for the tenant to go elsewhere. The land is then abandoned for a few years, covers itself with bush, which is subsequently cleared and burnt, cropped for a short time, and again abandoned. Another source of loss is found in the heavy tropical rain, which washes away finer soil particles as well as some of the plant food. This and other local problems are dealt with at some length.

The geological age of *Homo heidelbergensis* is discussed by Dr. Emil Werth in *Globus* (xcvi., p. 229); Schoetensack allocates this find to the earliest Diluvium (Nature, July 29, p. 132), but Werth, arguing from the associated remains, attributes it to the last but one inter-Glacial age, the Mindel-Riss-Interglazial of Penck. To this period belong the Mauer sand and the high terrace of the Rhine, since both lie below the later loess of the last (Würm) Ice age and the older loess of the last but one (Riss) Ice age. The Gravel of Süssenborn belongs to the same period, as it yields *Rhinoceros etruscus*, *Elephas trogontherii* (like the high terrace of the Rhine and the Norfolk bed), *Elephas meridionalis* (as found in Mindel-Riss-Interglazial stratum on the south side of the Alps), and also a horse allied to *Equus stenonis* of the Mauer sand. At St. Acheul, as at Mauer, there are three terraces, the middle one corresponding to the middle one on the Neckar, as it is covered by both sorts of loess. In the lower sand and gravel of this terrace of St. Acheul is human handiwork of characteristic Chellian form, which, according to Penck, belongs to the Mindel-Riss-Interglazial time. *Homo heidelbergensis* then lived exactly in the middle of the Ice-age period; the end of the Tertiary age was as remotely behind him as the old Palæolithic Chellian culture of his times is behind us. He does not represent the old diluvial Eolithic age, still less is he a type of Tertiary man. Werth considers that this conclusion modifies the arguments which have been based upon the character of the jaw, and he disputes Schoetensack's view that it is of a type prior to that of the anthropoids. He attributes the powerful development of the jaw to have arisen in response to an earlier stronger dentition, and accounts for the deterioration of the teeth by the discovery of fire to soften the food and the employment of stone implements, which did the work for which teeth were previously used.

The first section of an important paper by Prof. C. F. Marvin, on methods and apparatus for the observation and study of evaporation, appears in the *U.S. Monthly Weather Review* for April. The author points out that while, instrumentally, it is very easy to measure evaporation under certain conditions, it is very difficult to correlate the results obtained by different observers, not that the contributions are necessarily inaccurate, but because they are solutions of a complex problem not yet fully understood. In this section Prof. Marvin deals with the customary methods and their failings, and with the various equations, which he separates into two classes—(1) those developed from mathematical equations representing the phenomena of pure diffusion, and (2) partly rational and partly empirical equations intended to express the relation between evaporation and the meteorological conditions by which it is influenced. Section ii., which will be published subsequently, will deal with apparatus; the author will then describe a special instrument, devised by himself, which records simultaneously on the same sheet the wind, evaporation, and rainfall (if the evaporation pan is not sheltered from precipitation).

In the *Revue générale des Sciences* of October 30, M. L. Teisserenc de Bort gives an interesting account of an investigation of the meteorology of the tropics, based chiefly on observations with kites and registering balloons in the Atlantic between 35° N. and 8° S., and between the coast of Europe and 47° W. longitude. The author goes at some length into the history of the subject and the methods of launching and recovering the balloons, but we can here only briefly refer to the general results obtained. The N.E. trade wind was found to extend, on an average, to about a height of 1000 metres, then a zone was met with in which the winds came generally from N.W. These N.W. winds appeared to cease at about 10° from the point of convergence of the trade wind, which in summer is about 8° N. At a greater height the zone of winds with a southerly component, forming the anti-trade, was met with; on approaching the equator this zone was found at a lower altitude, being at about 1800 metres near Cape Verde Islands. Temperature first decreased rapidly with height; above 500–600 metres a zone with slight decrease, and extending with or without inversion up to about 2500 metres, was met with, as previously pointed out by Prof. Hergesell. In the neighbourhood of the anti-trade the temperature commenced to decrease regularly up to 14 or 15 kilometres. Above this height the so-called isothermal zone was found, the existence of which was pointed out by the author some years ago. These characteristics are analogous to those observed in temperate regions during a well-formed area of high barometrical pressure.

THE Bausch and Lomb Optical Company, 19 Thavies Inn, Holborn Circus, has published a new microscope chart for use in laboratories where instruction is given in practical microscopy. This appears to be becoming a recognised method of advertising with Continental and American microscope makers, although we are not aware that any English firm has yet issued such a chart. It is extremely well got-up, shows the mechanical and optical essentials of the instrument very well, as well as diagramatically representing the direction and path of the rays of light which pass from the illuminant and go to form the microscopic image. The chart may be obtained gratis by any college or medical institution, and it can be used with advantage wherever work is done with the microscope.

MESSRS. ERNEST LEITZ, of Wetzlar, Germany, and 9 Oxford Street, W., have issued a new edition of their catalogue of microscopes, and a separate one of microscopical accessories. It is interesting to note that Messrs. Leitz are always more nearly approaching the English type of stand in their new model microscopes; in one at least of their recent instruments the English type has been entirely adopted. They are also bringing out new achromatic condensers, and providing much more efficient arrangements for the centration of these on the microscope. Their new reflecting condenser for dark-ground illumination, which differs from any other in that it consists of spherical reflecting surfaces, is among the best to be obtained. They claim for it that not only is its correction of the highest order, but that the amount of light that actually reaches the object is greater than in any other appliance of a similar nature. In general, the character of the productions of this firm is such that workers who wish to obtain instruments for microscopy may well give attention to these new catalogues.

IN the course of his address to the Northern Architectural Association, an abstract of which appears in the *Builder* of November 13, the president, Mr. G. T. Brown, dealt with the question of architectural copyright. The law, as it stands at present, is that the client may demand, not only the whole of the drawings and specifications, but also the studies and detailed calculations, and there is nothing to prevent his making what use of them he pleases. Other buildings may even be carried out by their aid without the architect receiving any compensation for them whatever. Means are taken in other countries to protect the interests of the architectural profession, and the hope is expressed that a Government Bill will be introduced at an early date to deal with the matter.

AN interesting article on New York City bridges, by Mr. T. Kennard Thomson, appears in the *Engineering Magazine* for October. Among other bridges illustrated and described is the Williamsburg Bridge, which is claimed to be the most rigid long-span suspension bridge ever built. The main span is 1596 feet, and the total length of the bridge is 7250 feet, nearly one and a half miles. The stiffening trusses are about 40 feet deep; the four main cables are each made up of thirty-seven strands, each strand containing 208 wires, making a total of 31,784 wires in the four cables. Expansion and contraction and the effect of the live load produce a deflection at the centre of the span of 6 feet 9 inches, and yet this is a very rigid suspension bridge. The Brooklyn suspension bridge has a river span of 1595 feet, the total length being 6000 feet. Its centre rises and falls about 9 feet each way (18 feet in all), partly owing to the loading and partly to fluctuations in temperature. The extreme deflection of the new Blackwell's Island bridge is expected to be about 20 inches. This latter bridge is unique among long-span bridges in respect of the cantilever arms meeting in the centre without any intervening span.

MESSRS. CONSTABLE AND CO., LTD., have just published a cheap edition (2*s*. 6*d*. net) of Prof. H. H. Turner's "Modern Astronomy," originally issued in 1901, and reviewed in NATURE of March 21 of that year (vol. lxiii., p. 488). The book gives an admirable account of instruments, methods, and results of astronomy during the last quarter of the nineteenth century, and should now reach a wide circle of readers.

THE fifteenth volume of the new series of the "Reliquary and Illustrated Archæologist" has been published by Messrs. George Allen and Sons at the price of 12*s*. net. The volume contains the four quarterly parts issued this year, the contents of which have been referred to in these columns as the parts first appeared. It forms a handsome, well-illustrated book, which should appeal to all readers interested in early Pagan and Christian antiquities, mediæval architecture, the survivals of ancient usages, and similar subjects.

MESSRS. WITHERBY AND CO. have published a second edition of Mr. M. J. Nicoll's "Three Voyages of a Naturalist," being an account of many little known islands in three oceans visited by the *Valhalla*, R.Y.S. The original issue of the book was reviewed in NATURE for May 14, 1908 (vol. lxxviii., p. 32), when one of its numerous illustrations was reproduced. The only material alteration in the second edition is in chapter xx., where the statement has been corrected that Easter Island, when first discovered, was uninhabited.

A SECOND edition of "A Treatise on Concrete, Plain and Reinforced," by Dr. F. W. Taylor and Mr. S. E. Thompson, with chapters by various other writers, has been published by Messrs. John Wiley and Sons in New York, and by Messrs. Chapman and Hall, Ltd., in this country. The first edition was reviewed in our issue of March 15, 1906 (vol. lxxiii., p. 457). The second edition aims to cover the developments in the design and construction of reinforced concrete since 1905, and to this end more than two hundred pages of new matter have been added. The price of the new edition is five dollars.

MESSRS. BAIRD AND TATLOCK (LONDON), LTD., have sent us a copy of their latest catalogue of general apparatus. The comprehensive character of the catalogue will be gathered from the fact that it runs to 848 large pages. Sections are included in the list dealing with different types of laboratory and other benches, fume cupboards, and other fittings; the special apparatus required for physico-chemical experiments, and instruments necessary for milk, oil, paper, and water analysis, in addition to general bacteriological and chemical apparatus. The volume will make a very useful addition to the laboratory library of working books; its numerous illustrations, concise descriptions of the more complicated instruments, and orderly arrangement will prove real aids to the selection of laboratory apparatus.

The librarian of the Library of Congress, Washington, has issued two "Want Lists," each running to more than two hundred pages, one dealing with the publications of societies and the other with periodicals. In a prefatory note to each volume, librarians and secretaries of institutions receiving copies of the lists are asked to check them and to notify the Library of Congress of any duplicates at their disposal which may help to complete the files of the Washington library. We observe that certain copies of NATURE are in request; perhaps some of our readers may have duplicate copies of the following issues, now out of print, which the librarian of Congress would be glad to receive:—1899—May 4, June 15, 22, July 6 to August 10, September 14, and title and index; 1901—August 1, 16 to October 10, 24, 31, and title and index. Librarians are invited to send to the Library of Congress lists of their wants, as there is at Washington a stock of duplicates available for exchange.

OUR ASTRONOMICAL COLUMN.

Atmospheric Refraction.—The Rev. W. Hall, Chaplain Instructor, R.N., has circulated a typescript article on "Refraction in Relation to Astronomical Navigation." It is short and clearly expressed; nothing is assumed as already known, and yet the reader is taken to the furthest limits required for the writer's purpose. The article is therefore a model of what such articles should be.

For purposes of refraction, rays fall under three classes:—(1) a ray from a high star; (2) a ray from a low star; (3) a ray from the horizon finally reaching the observer's eye a few feet above sea-level, but ten miles from his horizon. The second ray is outside the scope of the article, as navigators ought not to observe low stars. The other two rays are considered in detail, and full advantage is taken of the simplifications rendered possible in one case by the altitude of the star and in the other by the thinness of the stratum of the atmosphere traversed. Proper warning is given that the state of the atmosphere at the horizon may not correspond to the barometer and thermometer readings on board ship.

The Spectrum of Halley's Comet.—Using a slitless spectroscope, attached to the Crossley telescope, Mr. W. H. Wright succeeded in photographing the spectrum of Halley's comet on October 22, about 180 days before the computed perihelion passage.

Two hours' effective exposure was given, the guiding being effected by a movable micrometer attached to the telescope. The plate shows a faint continuous spectrum extending from about λ 3750 to λ 5000, and there is no evidence of the existence of any bright lines or bands characteristic of most cometary spectra; the spectrum is too faint to determine the presence, or absence, of dark lines (Lick Observatory Bulletin, No. 167).

Seasonal Change on Mars.—Through the Kiel Centralstelle (Circular No. 115, November 18) Prof. Lowell announces that the first apparent Antarctic snowfall of the season has taken place on Mars. Two patches have appeared in latitude 65°, one in longitude 100°, the other in 190°.

Other changes and new features are announced by MM. Antoniadi, Quénisset, and J. Comas Sola, respectively, in the November number of the *Bulletin de la Société astronomique de France*. M. Antoniadi reproduces, on four plates, four drawings of the planet made during September and October, and gives several conclusions to which he has been led by his observations at this opposition. Among these we notice that he affirms the superiority of larger instruments in observations of Mars. He also finds that the grey areas are subject to great modifications of contour, although the Syrtis Major now has the same aspect as in 1864. As regards the objective existence of "canals," M. Antoniadi urges that care should be taken in the nomenclature; some of these features are undoubtedly real and persistent, others have an undulated appearance and are more or less fugitive. He concludes by suggesting that with more powerful equipment the apparent geometrical arrangements would give place to irregularities both of form and tone.

Among other observations, M. Quénisset directs attention to the unusual dimensions of the Lacus Mœris and to the apparent periodicity of a canal to the south-west of Nectar.

M. Sola describes his observations of the Lacus Solis, and believes he has seen it triple, while he suggests that the two canals, Nectar and Bathys, are really made up by alignments of small "lakes" imperfectly seen, the latter canal being much more easily seen than in many previous oppositions. Fons Juventæ, seen in 1907, has remained absolutely invisible to him during the present opposition.

The Perseid Meteors in 1909.—During July and August watch was kept, at the Lick Observatory, for the August meteors, and on nine nights 755 meteors were seen. A special watch was kept on August 10 and 11, and 220 meteors were seen. July Perseids were exceptionally scarce and faint, and the maximum of the shower occurred on August 11, the horary rate, during a continuous watch lasting from 11h. 17m to 14h. 41m., being 117. Mr. Oliver states that the radiant appeared to cover a large area, and there was difficulty in separating it from the radiants of the contemporaneous minor showers.

A Daylight Meteor.—Dr. Palisa records the telescopic appearance of a meteor on September 4 at 10.30 a.m. Whilst making a daylight observation of Castor he was looking through a 1·5-inch finder, having a field of 2°, and saw a bright object cross the field. The velocity was small, and the shape was rather square than circular; the direction was from east to west, and the object was surprisingly large, appearing at least as bright as Venus (*Astronomische Nachrichten*, No. 4367).

Spectroscopic Binaries.—In No. 3, vol. xxx., of the *Astrophysical Journal*, Dr. S. A. Mitchell publishes particulars of seven spectroscopic binaries, determined from plates taken at the Yerkes Observatory and measured at the Columbia University. The stars dealt with are β Equulei, β Trianguli, γ Lyræ, θ Virginis, o 78 Virginis, 24 o^2 Canis Majoris, and ζ Canis Majoris.

The "Annuaire" of the Bureau des Longitudes, 1910.—We have received a copy of this "Annuaire," which is too well known to require detailed description; but it should be remarked that, in accordance with the innovation of 1904, the chemical and physical data are given this year and geographical and statistical data omitted. Similarly, in the astronomical section, the tables of stellar parallaxes, double stars, proper motions, &c., are omitted, and a complete list of the elements of the minor planets is published; about 800 of these objects are now included. The "Annuaire" also contains articles on the reunion of the International Committee for the *Carte du Ciel*, and on tides.

CONFERENCE ON MALARIA IN INDIA.

A FURTHER stage in the campaign against malaria has been reached by the inauguration of a conference on malaria at Simla under Government auspices, a report of the proceedings of which appears in the *Pioneer Mail* of October 15 and 22.

The proceedings were opened with an address by the Viceroy, who, after welcoming the delegates on behalf of the Government, pointed out how grievously India has suffered from the scourge of malaria, which is probably responsible in an ordinary season for one million deaths in the year and for 100 million cases of fever that are not fatal. The prevention of malaria depended upon the extermination of the malaria-carrying mosquitoes, on the prevention of their bites, and on the prophylactic use of quinine. The extermination of the mosquito was largely a question of administration and finance and of the development of sanitation.

An address was then delivered by Colonel Leslie, I.M.S., Sanitary Commissioner with the Government of India. He said:—"It is obvious, if malaria is due solely to the bites of anopheles mosquitoes, that the extirpation of these mosquitoes will abolish malaria. The continuous use of quinine, even for a short time, is inconvenient, unpleasant to the individual, and difficult to carry out among a community. It is therefore evident that the best way to get rid of malaria is to destroy the mosquitoes. The only questions are, Can it be done? and, if it can, At what cost? It has been successfully done at Ismailia, but in conditions which were extraordinarily favourable, such, as I fear, occur very rarely, if they occur at all, in India."

Colonel Leslie then referred to the operations against mosquitoes conducted at Mian Mir by Captain James and Lieut. Christophers. The latter reported that a distinct effect was produced upon the malaria of troops and on the endemic index of the bazaars. This was, however, only evident in the beginning of the fever season, and could not be maintained. The failure of the operations appeared to be due to the passage of adult anopheles into the area from without. All the Mian Mir experiment showed was that success in operations against mosquitoes is not so easily gained as some people say. Where drainage is perfect, as in the case of Ismailia, the inhabitants can exterminate mosquitoes with little trouble; but where drainage is non-existent or bad, as at Mian Mir, it is practically impossible, by any means at present within their reach, for the inhabitants to destroy the mosquitoes.

After dealing with the question of prophylaxis by quinine, Colonel Leslie proceeded to formulate a scheme for a permanent organisation to deal with malaria in India, viz. a committee in each province of three or more members to obtain information and supervise local inquiries, and perhaps to control the distribution of quinine. Each provincial committee would delegate one of their members to attend a meeting of a general committee in Simla, this general committee consisting of the provincial delegates, the Sanitary Commissioner, representing the Government of India, with Major James as secretary. The Government of India would appoint a scientific committee, and a certain number of workers would be under the scientific committee, and when necessary workers might be deputed to serve under the provincial committees.

Major James, I.M.S., introduced a discussion upon the distribution of malaria in India, and dwelt upon the necessity for an investigation similar to that which Captain Christophers made in the Punjab, which should be begun in every province. He concluded that there are not extensive areas in India in which anti-malaria measures are urgently required; he doubted if there were more than half a dozen considerable areas in the Madras Presidency which would come within this category.

Captain S. R. Christophers, I.M.S., read a paper on a new statistical method of mapping epidemic disease, with special reference to malaria, and confined himself to a discussion of the returns of the Punjab. He suggested that in each district a list of the more unhealthy *paraos* (rest camps) could be maintained, and operations commenced upon each in turn with a view to (1) destroy mosquitoes and larvæ and get rid of their breeding ground; (2) render the wells mosquito-proof; (3) issue quinine free to the local inhabitants, and to place it at all times within their reach free of cost. These operations should result in lessening the infectivity of such places. Captain Christophers also read a paper on malaria in the Punjab, in which he discussed quinine prophylaxis.

Major Chaytor White, I.M.S., considered that the recommendations of past malaria conferences are costly, and almost prohibitively so, if undertaken annually. More should be done in the propagation of fish which prey on mosquito larvæ.

Papers were also read by Lieut.-Colonel Thornhill, on malaria in cantonments; by Major James, on problems relating to the use of quinine; and Major Wilkinson brought forward a revised scheme for the distribution of quinine by Government.

At the termination of the conference various conclusions and recommendations were drawn up under the following main headings:—(1) scientific investigation; (2) the agency by which investigations should be made; (3) practical measures: (*a*) extirpation of mosquitoes; (*b*) quinine treatment and prophylaxis; (*c*) education; (*d*) finance.

ECONOMIC ENTOMOLOGY IN THE UNITED STATES.

MAPLE trees grown in the United States are liable to severe injury from defoliation by caterpillars. In addition to the fall web-worm (*Hyphantria cunea*, Dru.) and tussock moth caterpillar (*Hemerocampa leucostigma*, Dru.) there is a common and troublesome species known as the green-striped maple-worm (*Anisota rubicunda*, Fab.), which attacks maples of all kinds, and feeds occasionally on box-elder and oak. In a bulletin recently issued by the United States Department of Agriculture Bureau of Entomology, the latter pest is described in some detail by Messrs. Howard and Chittenden. In another publication they describe the leopard moth (*Zeuzera pyrina*, Fab.), the larvæ of which cause severe injury to many deciduous trees in northern New Jersey and eastern New York. It has been successfully combated in the public parks of New York City by injecting carbon disulphide into the larval burrows in the bark. Mr. Chittenden describes the rose-chafer (*Macrodactylus subspinosus*, Fab.), a long-legged beetle of a light yellowish-brown colour, which appears suddenly and in vast swarms in certain years, usually towards the middle of June in the northern States and about two weeks earlier in the southern, overrunning vineyards and orchards, nurseries and gardens. In about a month or six weeks from the time of their first arrival, generally after they have done a vast amount of damage, the beetles disappear as suddenly as they came. No successful means of combating them is yet known, the difficulty being that any process, to be successful, must be applied almost continuously.

The control of the pear-thrips (*Euthrips pyri*, Daniel) has been for several years the principal problem confronting the growers of deciduous fruits in portions of central California. This insect, on account of its mode of attack and habits, has presented unusual difficulties in control. Adults emerge from the ground in late February and early March, just when most trees are breaking into bloom. Eggs are usually deposited in the blossom, fruit stems, and leaf petioles. The larvæ, after hatching out, feed for two or three weeks, then drop to the ground, where they form a tiny protecting cell, within which they remain during the rest of the year. The pupal changes take place within this cell in the ground during October, November, and December. As measures of control, Mr. Dudley Moulton recommends winter cultivation followed by March and April spraying with tobacco extract.

The life-history of the greenhouse thrips (*Heliothrips haemorrhoidalis*, Bouché) is described by Mr. H. M. Russell. The damage caused by this insect is confined to the foliage of ornamental plants. Adults and larvæ both obtain their food by puncturing the epidermis of the leaf with their sharp mouth-parts and sucking out the sap. Fumigation with nicotine or with hydrocyanic acid gas were found to be effective methods of control.

Mr. A. L. Quaintance, who is in charge of deciduous fruit insect investigations, describes a new genus of Aleyrodidæ, *Paraleyrodes* (*aleurodicus*) *perseae*, Quaintance, found on orange trees and other plants in Florida. The adult is buff or pinkish in colour, and marked with white. The wings are whitish and lie almost flat along the dorsum, but do not meet along the middle line. A large amount of flocculent white wax is secreted over the leaf surface in the depressions in which the sluggish adults rest. From the same section of the Bureau is issued a description, by Mr. Hammar, of the cigar-case bearer (*Coleophora fletcherella*, Fernald), which damages the foliage and fruit of apple and pear trees. The name is given because of the curiously shaped cases, resembling cigars, made by the larvæ. Arsenical sprays were found effective in keeping it down. Messrs. Foster and Jones publish some additional observations on the lesser apple-worm (*Enarmonia prunivora*, Walsh), which is prevalent throughout the apple-growing district east of the Rocky Mountains. Late broods do a considerable amount of damage in autumn, and some of the larvæ work in the fruit for weeks after the crop is harvested. The methods adopted for keeping down the codling moth have, so far, proved effective in checking serious injury by this pest.

The regions of Virginia surrounding the Chesapeake Bay probably produce more early potatoes than any other part of the eastern States, the annual value of the crop approaching 6,000,000 dollars. Little damage is caused by blight, but the Colorado potato-beetle (*Leptinotarsa decemlineata*, Say) is a serious pest, and only very crude methods are adopted for keeping it in check, because of the prevalence of negro labour and the scarcity of capable white help. Mr. Popenoe gives a description of the pest and of the damage it does, and describes experiments in which three applications of lead arsenate mixed with Bordeaux mixture, the first about the time the eggs begin to hatch, and the others at intervals of three weeks, sufficed to control it.

Some new breeding records of the coffee-bean weevil (*Araecerus fasciculatus*, De Geer) are published by Mr. Tucker. He found the larval and pupal stages in some dried maize stalks, and obtained evidence that the insect causes injury to the maize plant. The attacks begin in the green stalks before the corn matures, and thus cause stunted ears. This weevil has also been found in the berries of the China berry tree.

Stringent laws are in operation in most of the States with regard to the importation of nursery stock. It is commonly necessary to notify the State entomologist within twenty-four hours of the arrival of the stock, and to fumigate satisfactorily. The laws of the different States are not all alike, and Mr. Burgess has collected in a short pamphlet the requirements which must be complied with by those making inter-State shipments of nursery stock. The pamphlet will form an interesting study for those who are agitating for some State supervision in this country.

THE METHODS OF MATHEMATICS.[1]

THE position assigned to mathematics in the educational system of every civilised country seems to mark it out as an essential element of mental culture, but an examination of the arguments that have been put forward from time to time to justify this position reveals a diversity of view that is at first sight disquieting.

Of those who acknowledge the value of mathematics there are many who see that value almost solely in its usefulness, in the help it brings to other sciences. Not unnaturally, those who are absorbed in the work of applied science are apt to turn away from the more abstract developments of modern mathematics; even the men whose special pursuits call for constant applications of mathematical processes, as in physics and engineering, can hardly be blamed if they lay special emphasis on those elements of a mathematical training that are of immediate application to their daily work. Yet it is not this aspect of mathematics that is usually present to the professional mathematician when he seeks to uphold the position of his subject in an educational system.

Mathematics may be assigned its place for a different reason. To those who reject the argument from utility, mathematics is not the humble auxiliary of other sciences, but is itself the one genuine science; it often comes to the aid of other sciences, but does not depend for the justification of its existence on the help it may be able to bring. From the adherents of this view come the familiar arguments for the disciplinary value of a mathematical training in which deductive logic is given a prominent place.

The question naturally arises whether these two aspects of mathematics are incompatible. To the teacher, whether in school or in college, the question is of prime importance; for the whole scheme of study and the methods of instruction will be found in the long run to be determined by the general attitude that is taken up with respect to the value of the subject. At the present time there is considerable uncertainty in the minds of teachers regarding the methods of school mathematics, and many of the older men are disposed to look unfavourably on recent changes as tending to impair the disciplinary effects of a mathematical training.

It may help us to understand more clearly the points at issue if we consider for a little the trend of mathematical inquiry during the nineteenth century. It is not necessary that I should sketch even in the roughest outline the development of mathematical science in that period; it will be sufficient for my purpose to indicate one dominant feature of the mathematical methods that were introduced in the early years of that century and that revolutionised the treatment of pure mathematics before it had reached its close.

During the eighteenth century the infinitesimal calculus and the doctrine of infinite series enabled mathematicians to investigate problems, intractable by the older methods, with a facility that led to a wide extension of the field of mathematical inquiry and to an enormous accumulation of results. In this period interest was centred less in demonstrations than in results, which were often reached by methods of a strange character, and sometimes, indeed, seem so absurd in themselves that we find it hard to understand how they were ever promulgated. Induction played a most important part in the discovery of theorems, and these inductions were often made from insufficient data and too seldom verified by subsequent tests. When the novelty of the processes had worn off, the necessity for a critical examination of their legitimacy became evident, and this examination was one of the tasks of the nineteenth century. It should be noted, however, that the great critics were also great creators; the criticism of the methods of mathematics was accompanied by a wide extension of its domain.

Of those who first saw the necessity for criticism and set themselves to the task were Gauss, Cauchy, and Abel. Gauss was first in the field, but, for various reasons, his work was long neglected. It was not until the publication in 1821 of Cauchy's "Cours d'Analyse" that the attention of mathematicians was effectively directed to the question.

Geometry in the hands of the Greek mathematicians had been reduced to a system of logically consistent truth; from assumed definitions, axioms, and postulates the various theorems of geometry were derived by the methods of formal logic, and Euclid's "Elements" were for centuries the standard of mathematical rigour. Algebra, or, in modern terminology, analysis, was of much later growth, and Cauchy's reference to the rigour that is demanded in geometry simply means that the time had come when the revision of principles and methods that the Greek mathematicians had effected in geometry should be carried out for algebra or analysis. The eighteenth century was a period of great activity in the development of analysis, and it is not surprising that the pioneers of this development should have been more interested in the resources of the country they were opening up than in the roads they followed. Their methods of mathematical inquiry were not limited by the traditional canons of Greek geometry; they included induction as well as deduction, there was constant appeal to intuition, and general theorems in mathematics were often established from physical considerations. The usefulness of mathematics as an aid in the investigation of the phenomena of the material world was the predominating feature of the period. The aim of Gauss, Cauchy, Abel, and their coadjutors was, in general terms, to do for analysis what the Greeks had done for geometry, and to make mathematics an independent science by clearly defining its province, stating the postulates from which the science starts and developing the consequences by the laws of logical operation without appeal to extraneous considerations.

The work of scrutinising the methods of analysis was vigorously pursued throughout the nineteenth century, and exerted a far-reaching influence. The notion of continuity, which seems so naturally to attach to geometrical quantity, required to be formulated in such a way that it would be amenable to calculation. Current conceptions of number were too vague, and it was found necessary to analyse more carefully the notion of numerical quantity so as to frame definitions and to establish rules of operation for the continuous variable of analysis. The so-called imaginary numbers had been long in use, but their existence was of a precarious nature, and the right to use such numbers had to be justified.

As will be easily understood, many of these discussions are of a very abstract nature, but they have provided a solid foundation for the operations of mathematics, of geometry as well as of analysis.

---

[1] From the inaugural address delivered on October 11 by Dr. George A. Gibson, Professor of Mathematics in the University of Glasgow.

The movement, however, was not without its disadvantages. Mathematics gradually became more and more abstract, and the relations of mathematics to the applied sciences tended to fall into the background. On one hand it was manifestly impossible for the physicist and the engineer to keep themselves abreast of the developments of pure mathematics; on the other, the rapid extension of physics and engineering made it difficult for the mathematician, even when he had the desire, to understand the problems in the investigation of which mathematics might have been useful. The mathematics of the secondary schools was not affected to any considerable extent by the critical movement, but it probably became more formal and lost contact with the applied sciences.

Towards the close of the century complaints were rife, especially among the engineering community, that mathematics had lost touch with reality, and demands were made for a radical change in the mathematical training of the schoolboy. The feelings of dissatisfaction were not confined to any one group, and men who represented the most widely separated interests took a keen and active part in the discussions. Many of the views expressed respecting the methods of mathematics were far from new, but the emphasis with which they were urged may perhaps be taken as an indication of the extent to which, in the opinion of many competent judges, the deductive element in mathematics had overshadowed all others.

It may be conceded that, in the claims that have often been advanced for the efficiency of mathematics as an educational instrument, far too much has been made of the deductive aspect of mathematical studies; but in view of what has been said about the character of eighteenth-century mathematical methods, the assertion that mathematics knows nothing of induction is surely inaccurate. It is besides, I believe, a complete misunderstanding of the critical school to suppose that induction is barred as a mathematical method. By induction I do not here mean simply what is called "mathematical induction" or that method of demonstration which shows that if a theorem is true in one case it is true for the succeeding one; I am using the word in the sense it generally bears in speaking of scientific method. Induction as a method of discovering new truths or generalising known theorems has always been recognised to be of very great value, and is in constant use in advanced as well as in elementary mathematics. The critical objection to it was solely in respect of its use in a *systematic* development of mathematical truth (Euclid's "Elements," for example, embody a systematic development of geometry in which the theorems are linked together by a chain of deductive reasoning). As Weierstrass, one of the greatest of the critics, says, "it is a matter of course that every road must be open to the searcher as long as he seeks; it is only a question of the systematic demonstration."

In any discussion of mathematical methods it is important to bear in mind that the conviction of the validity of a theorem is not dependent on any single method of proof, even though one may strive to furnish a demonstration that conforms to some prescribed system. In mathematics, as in other sciences, conviction comes from many quarters, and one might almost say that where higher mathematics enters into the work of the physicist or the engineer the conviction that comes from the logical consistency of a mathematical demonstration is less important than the conviction that is due to insight into the physical facts and to the perception of the correspondence between the mathematical representation and the data of experiment. I think that pure mathematicians have not always given due weight to the instinct of the trained experimenter, and that, for the physicist, the true source of the conviction of the validity of "existence theorems" is often to be found in the disciplined imagination rather than in the cogency of the mathematical analysis. On similar grounds the essential accuracy of many of the results obtained by eighteenth-century mathematicians may be explained; their practical instincts prevented them from pushing a theory or method too far.

Now if it be granted that induction is a recognised mathematical method, it is hard to understand how observation and experiment can be dispensed with, because these are essential preliminaries to induction. In the development of mathematical knowledge it is quite certain that the predominance of deductive methods was of comparatively late growth, and that in the earlier stages observation played the leading part. It is unfortunate that so little of the work of the early Greek geometers has been preserved, but it is undoubtedly the case that geometry in its beginnings was essentially surveying or mensuration, and many of Euclid's theorems were known long before they were incorporated in a systematic treatise. There was, in fact, a "natural history" stage in the development of scientific geometry which the perfection of Euclid's deductive treatise has tended to obscure. The stage in which geometry appears as a logically consistent system was preceded by a period in which geometrical theorems were discovered as the result of observation and the consideration of many particular cases; in this formative period induction based on observation had full scope.

The evolution of scientific algebra has followed similar lines. The introduction of fractions in arithmetic, for example, and of negative and imaginary numbers in algebra, was due to their convenience in handling practical problems; the rules for their use were usually established, so far as proof was considered necessary, by appealing to numerous particular cases. The logical consistency of the scheme of operations was seldom discussed; so long as a rule led to results which gave a solution of the particular problems under investigation the need for a systematic presentation was not even felt. This stage—the "natural history" stage—of the development of algebra is well known to us by the works that have been preserved of the early writers on algebra; it would perhaps be true to say that a great part of elementary algebra has not advanced in actual school teaching beyond this stage.

The advance of mathematics to the position of a logically consistent system of truth has thus been governed by the same principles as regulate the progress of every science. Induction based on observation and confirmed by tests or verifications was constantly employed in extending the range of the science, and it was only gradually that deduction became the predominant, though never the exclusive, method of mathematical study.

In the recent discussions on elementary mathematics the guiding principle that has emerged seems to me to be the explicit recognition of the essential part that observation and induction play in the acquisition of mathematical knowledge. With this recognition is associated the idea that in the early training of the pupil it is scientifically unsound and practically hurtful to emphasise the deductive element; his training should, in its broad outlines, be modelled on the course that the historical development of mathematics has followed. Mathematics has now reached the stage in which it is possible to treat it as a deductive science, but it does not follow that it is either necessary or possible to teach it to beginners entirely as a deductive science. To do so is to mistake the meaning of its history and to deprive it of its place as an exponent of scientific method. Observation, classification, and induction are essential elements of scientific method, and these are well illustrated in the historical development of mathematics. The recent discussions have shown that, in the opinion of many experienced teachers, it is not only possible, but necessary, to make full use of these methods in mathematical teaching, and the conviction is widely held that they are of special importance in geometry, the branch of elementary mathematics where deduction has so long had the leading place. The excellence of the intellectual discipline to be obtained from a study of Euclid is, in my opinion, not to be questioned, but I think there is no doubt that it is contrary to all scientific order to take Euclid as our guide for an introduction to geometry. It is necessary for the pupil to acquire a knowledge of the forms of material objects before he can reasonably be expected to demonstrate the geometrical properties that are implied in the definitions of geometrical bodies. In acquiring this knowledge observation and classification are essential, and deductive reasoning will have little place. The knowledge thus gained may be quite entitled to the name of scientific; if the course is carefully planned and carried out, it will be quite possible to obtain a system that is not a mere aggregate of isolated details, but a coherent structure. The importance of a practical course is now generally recognised in its bearing on deductive geometry; its value, however, in relation to the appreciation of scientific method is equally great.

The early stages of algebra are usually found to be very difficult, and are too often of little scientific value; the subject is more abstract than geometry, and the temptation to let the teaching degenerate into a mere mechanical application of rules is very great. I cannot but think, however, that the spirit of De Morgan's chapter on "The Study of Algebra" in his book "On the Study and Difficulties of Mathematics," written so long ago as 1831, is in full accord with scientific method, and is worthy of being more completely realised in practice than it has yet been. I cannot refrain from quoting a few sentences that indicate his view of the way in which a reasonable conviction may be obtained. After pointing out the value of *mathematical* induction, he says:—"The beginner is obliged to content himself with a less rigorous species of proof though equally conclusive as far as moral certainty is concerned. Unable to grasp the generalisations with which the more advanced student is familiar, he must satisfy himself of the truth of general theorems by observing a number of particular simple instances which he is able to comprehend. For example, we would ask anyone who has gone over this ground whether he derived more certainty as to the truth of the binomial theorem from the general demonstration (if indeed he was suffered to see it so early in his career), or from observation of its truth in the particular cases of the development of $(a+b)^2$, $(a+b)^3$, &c., substantiated by ordinary multiplication. We believe firmly that to the mass of young students general demonstrations afford no conviction whatever; and that the same may be said of every species of mathematical reasoning when it is entirely new."

There can, I think, be no doubt that it is now generally recognised that it is in accordance with true scientific method to keep the purely deductive element in the background so far as the early training in mathematics is concerned, and that by so doing the general methods characteristic of scientific procedure are more fully illustrated. This recognition, however, does not imply that the characteristically deductive side of a mathematical training is to be neglected; it means rather that deduction, which is surely a scientific method, will be used with a fuller comprehension of its place and even of its necessity. The time and the manner of the passage to deduction are not to be easily decided; much depends on the pupil, and it is one of the hardest tasks of the teacher to determine the appropriate correlation of methods. Induction is essential as an instrument of research, but deduction is also essential to the systematic development of mathematical science, and no training in mathematics can be considered satisfactory that does not show the complete process by which mathematical knowledge advances from the stage of observation to that of a science in which deduction plays the principal part in the coordination of its contents.

In this conception of elementary mathematics we have the leading characteristics of scientific method, and have them, as I think, in great simplicity. It is on this ground that the study of mathematics seems to me to be a valuable, if not indeed an essential, factor of modern education. Science has effected a great revolution in the material conditions of life, but it has also produced a profound change in the mental attitude of all thinking men. Our civilisation is not intelligible unless account is taken of the influences, material and intellectual, that are due to the progress of science. The right study of mathematics, even in its humblest forms, offers an easily accessible road to the appreciation of the fundamental characteristics of scientific method.

It is of interest to note further that the more recent methods of treating elementary mathematics, which are inductive rather than deductive in their character, lead in a natural manner to an appreciation of some of the cardinal ideas and methods of pure mathematics. Thus the notion of a continuously varying function, the conception of a limit and the method of successive approximation, cannot fail to be impressed upon a pupil who has been adequately disciplined in graph tracing.

The complexity of the problems confronting modern scientific research, with the vast accumulation of detail so characteristic of it, demands a careful training in the discrimination of the essential from the accidental, in the search for the underlying principles that coordinate or explain the details, and in the selection of the most general points of view from which to survey the field that has been worked. In this training, quite apart from the direct utility of the more advanced mathematical processes, much assistance is to be obtained from a mathematical course; the processes of thought involved in any serious study of mechanical or physical phenomena have much in common with those developed in the study of mathematics. It is the special task of the teacher to determine the extent to which the rigorous methods of pure mathematics are to be carried. Rigour is relative, not absolute, and will always be conditioned by circumstances of subject and person, and even by the prevailing fashions of the day. Restrictions corresponding to the nature of the subject and to the intellectual development of the student have always been recognised as essential. Many assumptions are either tacitly or explicitly made, fundamental theorems the demonstration of which offers special difficulty are frankly taken for granted until the necessity or the expediency of their demonstration arises and the logical completeness of a course is therefore impaired; but progress is all but impossible on any other lines, and much may be gained from demonstrations that are in parts confessedly incomplete. The real danger to the student lies in a demonstration that has the appearance of being complete and yet conceals serious assumptions. It is a great advantage that in mathematics general theorems can often be tested by particular cases that are easily handled, and practice of this kind will often produce that working conviction which is so essential for fruitful applications. One is reminded in such cases of the saying attributed to D'Alembert, "Go forward and faith will come to you."

Up to this point I have been considering the methods of mathematics almost solely in relation to the function of mathematics as a factor of general education or as the auxiliary of the applied sciences in their more elementary stages. The considerations that I have thus hastily sketched seem to me to involve the conclusion that this phase of mathematics is to be justified neither by its usefulness alone nor by its disciplinary power alone, but by the degree to which the training combines these elements. In a properly balanced mathematical course the characteristic features of scientific method will receive due recognition, and the mental horizon of the learner will be gradually enlarged; but the choice of material and of method will prepare him for the application of mathematical processes in various fields, and the study as a whole will powerfully react on his mental development.

It must not be forgotten, however, that the claims of mathematics are not exhausted by such developments as I have indicated. I have deliberately avoided all reference to what is called pure mathematics, and have confined myself to those aspects of mathematical study that are of general interest. It is difficult for anyone who is not a professed student of mathematics to realise the position of the subject in its modern developments. The great critics of the nineteenth century were not less successful in extending the boundaries of mathematical science than in securing by a just title the territory acquired, and to-day the range of subjects that fall properly within the domain of mathematics has an extent that the contemporaries of Newton and Leibnitz never dreamed of. As the result of their labours mathematics ranks as a science worthy of cultivation for the intrinsic value of the conceptions which it embodies, for the appeal it makes to the constructive imagination, for the light it casts on the processes of thought, and for the inherent beauty of form that characterises many of the theories comprised within its domain; but any attempt at reviewing, within the limits of time allotted to me, the present state of the science would certainly fail to give any adequate conception of the nature of its contents. To the mathematical student, however, the assurance can be given that he need not fear that the science is complete and that all the problems it presents have been finally solved. Abstract as these investigations often are, there is ample room for the application of those general principles of scientific research which his earlier training will have helped to develop, and the final test of his mathematical powers will be found in the success with which he extends the scope and methods of the science.

Mathematics as we know it to-day is in living contact with experimental science on the one side; on the other it borders on the domain of philosophy; to each it has some contribution to offer, and in the words of Weierstrass "a mathematician who is not something of a poet will never be a complete mathematician." Is it not, then, a subject worthy of a place in university studies?

DEVELOPMENTS OF ELECTRICAL ENGINEERING.[1]

THIS address deals with a few only of the many recent developments in electrical plant and its application to industrial purposes.

Generators.

The modern tendency is to instal very large units. This is partly due to the large demand made on the power house and the desire to restrict the number of units, and partly to the fact that the advantages of the steam turbine over the reciprocating engine become more pronounced with the increased size of the unit. The General Electric Company of New York have built several turbo-alternators of 14,000-kw., and the British Westinghouse Company inform me that it would be quite feasible to build sets of 15,000 kw. up to 15,000 volts pressure. In water-driven alternators, also, the tendency is towards large units. Thus the power house of the Norwegian Nitrogen Company at Svälgfos, near Notodden, has been fitted with four turbine-driven three-phasers, each for 10,500 kilovolt-ampere, and developing 7000 kw. at 10,000 volts. It is obvious that in these circumstances special ventilating arrangements become necessary. Dr. Kloss, in a paper read before our Institution about a year ago, has pointed out that the scientific way of ventilating turbo-dynamos is to take the air from the outside and discharge it to the outside of the engine-room. It is important that only clean air be used, and for this reason air filters are built into the inlet ducts. These are formed of pockets of porous cloth extended over wooden frames, and so placed that the dust which settles on the cloth may be removed by beating or with a vacuum cleaner. Washing or chemical cleaning is only required after some years of use.

In most modern electricity works the circulating and air pumps are driven by electric motors, but this method has been replaced at the works of the Allgemeine Elektricitäts Gesellschaft by turbo-driven centrifugal pumps. No piston pumps at all are used, and the feed may be regulated without paying attention to the feed pump. The feed water obtained by this method is absolutely free from air, and only 5 per cent. of make-up for the feed is required. Since no piston engines of any kind are used, there is no need for oil filters.

An important development in turbo sets was initiated about ten years ago by Prof. Rateau with his exhaust steam turbine. The cost of adding exhaust steam turbo sets to an existing installation of large size may be taken at from 6*l.* to 10*l.* per kilowatt exclusive of thermal storage. The commercial advantage is considerable. Thus in the Osterfeld Mine a Rateau plant installed at a cost of 53,000*l.* has resulted in an annual saving of about 20,000*l.*

The desire to reduce the cost and complication of switchgear and to make paralleling easy has led to the use of non-synchronous machines as generators. The rotor may be a squirrel-cage of very simple construction and requiring hardly any insulation, no matter how high the pressure produced by the stator may be. The mechanical construction is easier than that of the revolving field of an ordinary turbo-alternator, and since the air space can be made small, the power factor is high. A 5000-kw. non-synchronous generator was last year added to the plant of the Inter-borough Rapid Transit Company, New York.

There is some difficulty in the design of turbo-alternators for very low periodicity, since the speed becomes insufficient for the satisfactory working of the turbine. To meet such cases Mr. E. Ziehl has devised a type of alternator which he calls a "double-field generator." The principle may be explained as follows: Imagine a non-synchronous motor having precisely the same three-phase winding in stator and rotor, and let the circuits be connected either in series or parallel in such way that a three-phase current sent through the machine will produce fields which in stator and rotor revolve in opposite sense. If now the rotor be driven by power in a sense opposite to that of its own field and with a speed corresponding to twice the frequency, the field produced by the rotor currents will in magnitude and direction of motion be identical with that produced by the stator currents. Thus each of the two windings contributes one-half the field common to both. At the same time the demagnetising action of each winding is eliminated by that of the other. Since the E.M.F. is generated in both windings, only half the flux as compared to a synchronous generator is required; hence less hysteresis loss, smaller radial depth of stampings, and less copper weight. The paralleling is easy; the speed need only be approximately right, and if coupled up in a wrong phase position no damage is done, since the inductance is then very great.

Transformers.

In transformers also there is to be noticed a general tendency towards large units, which is not surprising if one considers that for the calcium-carbide industry alone about half a million horse-power in generating plant has been installed throughout Europe, and that most of the power has to flow through transformers to the carbide furnaces.

The General Electric Company of America have built several 10,000-kw. three-phase transformers working at 60 frequency, and giving a pressure of 100,000 volts. The largest European transformers of which I could find a record are some made by the Siemens-Schuckert Werke. They are three-phase 6750-kilovolt-ampere capacity oil cooled, for 66,000 volts on the high-pressure side. The use of oil as a filling medium has made it possible to build transformers for very high pressure. In one American power-transmission plant now under construction the step-up transformers are intended to raise the pressure to 110,000 volts, but even higher pressures can be obtained. Transformers giving extremely high pressure on the secondary are used for testing insulators and insulating material. A transformer of this kind has recently been made by Messrs. Brown-Boveri. It is a 50-kilovolt-ampere transformer wound for a primary pressure of 1000 volts and giving on the secondary 250,000 volts, but even this has been exceeded when the transformer was used in testing the dielectric strength of insulators. From a curve referring to such tests which the makers have sent me I find that the highest pressure recorded was 310,000 volts.

The reduction in weight of transformers due to the use of alloyed iron, large units, and vigorous cooling is very remarkable. As an example of good modern practice, I take a Brown-Boveri transformer where the active material weighs only 3·1 kg. per kilowatt, and the efficiency is 98·6 per cent. at full non-inductive load. In an Oerlikon 3500-kw. transformer the active iron only weighs 7 tons, being at the rate of 2 kg. per kilowatt output. The largest self-cooling oil transformers of which I know are some 1200-kw. three-phase 40-frequency 5000-volt transformers made by the British Westinghouse Company, but for larger unit artificial cooling becomes necessary.

For furnace work it is well to allow a rather large inductive drop so as to reduce the rush of current in the event of a short circuit in the furnace. This means wide spaces between primary and secondary coils, but it also involves the necessity for good mechanical support. The mechanical forces acting on the individual coils may become considerable, and this is probably the reason why some makers prefer the core type with concentric cylindrical coils, the cylinder being the best shape for resisting radial forces.

---

[1] Abridged from an address delivered before the Institution of Electrical Engineers on November 11 by Prof. Gisbert Kapp, president of the institution.

Motors.

In three-phase motors for railway work, speed regulation has hitherto been obtained either by some kind of cascade arrangement or by changing the number of poles. In either case the rotor has slip-rings, a complication one would gladly avoid. This is now possible, thanks to an ingenious design worked out by Mr. Aichele, the chief designer of Messrs. Brown-Boveri. The motor has been applied in their latest Simplon locomotives. Its rotor is simply a squirrel-cage, and has no slip-rings and no outside electrical connections whatever. The stator has two distinct windings, one for 16 and the other for 12 poles, and each winding can by means of a pole-changer be so grouped as to produce half its normal number of poles. There are thus four normal speeds possible, corresponding respectively to 16, 12, 8, and 6 poles, or to a train speed of from 26 to 70 km. per hour.

A remarkable improvement in single-phase motors has been devised by Mr. Deri, and practically developed by Messrs. Brown-Boveri. Mr. Deri's motor is a "repulsion-motor," with movable *and* fixed brushes. The effect of shifting the former is analogous to changing the impressed voltage on an ordinary continuous-current series motor, and thus by adjusting the brushes the torque and speed may be regulated. This property renders the Deri motor valuable in all cases where delicate speed regulation is essential. It is largely used for working passenger lifts and other hoisting machinery, and also for driving ring-spinning frames, the speed regulation in the latter case being automatic. The result of automatic speed regulation is an increased output from the ring-spinning frames. Another application is for electric railway working, to which I shall refer later.

The Electric Transmission of Power.

There has been a considerable development in this branch of applied electricity in late years, but the development has been on different lines in different countries corresponding to their various topographical, industrial, and commercial conditions. With us it is not so much a question of carrying power a long way as of distributing large amounts of power at numerous points within a restricted and densely populated area. In so-called water-power countries the distance between the source of the power and the points of its delivery is very much greater than in England, and hence the necessity of using much higher pressures in the transmission lines. In raising the pressure a limit is eventually reached at which dispersion of power becomes serious. This critical potential difference in virtual kilovolts is:—

$$\mathrm{KV}=\frac{0{\cdot}115b}{0{\cdot}5+r}\left(\frac{1}{1+0{\cdot}013v}\right)r\log\frac{s}{r}.$$

Here *b* is the barometric pressure in mm. of mercury, *r* is the radius of the wire in cm., *s* the distance between the two wires in cm., and *v* is Mershon's "vapour product," namely, the pressure of saturated steam in mm. of mercury at the given temperature multiplied by the relative humidity, or the ratio $\frac{\text{actual moisture}}{\text{possible moisture}}$.

The protection of power lines against pressure surges due to atmospheric or other causes is a very important matter.

It is well known that the connection of an underground cable with an overhead line constitutes a special danger to the cable from atmospheric discharges. To protect the cable, Mr. Semenza, of Milan, uses a kind of gigantic Faraday cage surrounding the point where the overhead lines are connected to the cables by transformers. The iron parts of the structure are earthed, the roof and the window-frames are of iron, and under the plastering of the walls there is iron netting. If a capacity and inductance tuned to somewhere near the frequency of the surge are placed in series and connected to line and cage, a current of that particular frequency will flow to earth as if the connection were direct. Even if the frequency were only approximately that to which the set was tuned, the reactance would not be excessive and the protection would be sufficient. Thus a set tuned to 1 million frequency would at 10 million frequency have a reactance of 158 ohms and at 100,000 frequency a reactance of 165 ohms. A set tuned to 100,000 frequency would at 20,000 frequency have a reactance of 192 ohms. A set for 1 million frequency may conveniently be formed of two Moscicki condensers in parallel, having together a capacity of 0·01 mf. and an inductance of 2·54 microhenry. The latter is obtained by two turns of 2 mm. copper wire 50 cm. in diameter. A set for 100,000 frequency would require eight condensers in parallel and a coil of ten turns. For the ordinary working frequencies up to 50 either set has of course a practically infinite reactance, that is to say, it has no effect on the power current. The Milan translating station has been at work now for about two years with perfect success. It should be noted that the system not only protects against lightning discharges, but against any abnormal rise of pressure, in so far as this is caused by a high-frequency surge.

Whilst on the subject of safety devices in connection with power transmission, I must refer to another recent invention, the object of which is the prevention of the infiltration of high-pressure current into low-pressure lines. That such a device is urgently needed is shown by the lamentable accident which happened last August in Olgiate, where several persons were killed by contact with nominally low-pressure lighting circuits. The danger of a short or a leak between high- and low-pressure circuits does not lie in the transformer. This can be made absolutely safe; but the switches and leads to the transformer, and especially the outside lines where there are miles of them, are a source of danger. A broken wire or a branch of a tree blown across two lines by the wind are possibilities from which no excellence of workmanship can guard us. Some means should therefore always be provided to cut off the current automatically in the low-pressure circuit as soon as its potential to earth exceeds a predetermined limit. Such an instrument was perfected last year by Mr. Arcioni, of Milan, and is now being gradually taken up on the Continent. Last year I tested the Arcioni safety device on the Milan system, making artificial leaks from the 6000-volt network to a local secondary lighting circuit, and found the action absolutely trustworthy.

The commercial development of electric power distribution on a large scale in this country by companies established for this purpose may be said to have begun with the present century. The public generally, and even some engineers, are still under the impression that a country of abundant water-power offers better opportunities for electric power distribution than a country of cheap coal, but that this is in reality not so is demonstrated by the great development which power supply has reached in this country. In the country of waterfalls industries have to be introduced in order to utilise the power made available through electric transmission, whilst in the coal country highly developed industries of different kinds are already there. As regards capital outlay, the advantage lies generally with the thermal station, quite apart from the extra cost of a steam reserve, which, for at least part of the power, in many cases is unavoidable. If, then, we speak of the cheap water-power of Swiss and Italian hydro-electric works, we do not mean that those works can produce power more cheaply than English thermal stations, but that they can produce it more cheaply than if they had to use imported coal.

Although in this country we have only little water-power, the deficiency is made up by other sources of energy which now mostly run to waste. Mr. C. H. Merz estimates that within the area served by the North-east Coast Power System the gas obtained as a by-product of the coke ovens could be made to yield continuously 150,000 horse-power if burned under boilers, and 250,000 horse-power if used in internal-combustion engines. It is the merit of Mr. Merz to have recognised the enormous commercial importance of these sources of energy, and to have already made a beginning with their utilisation by the establishment of what he calls "waste heat stations."

Electric Railways.

For main lines alternating current is unavoidable, and the only question on which there may be still difference of opinion is whether the current shall be three-phase or single-phase. Electricians prefer the former, railway men the latter mainly on account of the greater simplicity of the overhead work. As the railway men are in reality the customers who give the order to the electrical engineer, it seems likely that the single-phase system will be the one more generally adopted; and, indeed, a very respectable beginning has within the last four years already been made on the Continent, where single-phase vehicles aggregating more than 100,000 horse-power are at work or on order.

In Italy considerable progress is also being made. The Government has decided to electrify eleven sections on the State Railways, aggregating 337 miles of track, but on the three-phase system. Thus the battle of the phases is still undecided. The decision of the Italian State Railways to use three-phases, whilst in Germany, Austria, England, Sweden, and America the single-phase system is preferred, is highly interesting. Mr. Verola, the chief engineer of the electrical department of the Italian State Railways, was good enough to explain the reason for this choice. The following is an abstract of his letter:—

"In the case of the three lines (Pontodecimo-Busalla, Bardonecchia Modane, and Savona-Ceva) which are about to be opened, the service is extremely heavy, trains of 400 tons and over having to be hauled up on long grades of 25 to 35 per mil. at a speed of 45 km. per hour. With the three-phase system it is possible to comply with these conditions by using two locomotives. These weigh each 60 tons, and develop each at the 1-hour rating 2000 horse-power. With the single-phase system the weight of the motors would be at least doubled, resulting in a greater expenditure of energy. The advantages of wider speed adjustment in running and better efficiency in starting are not of importance on these lines. It is probable that also some future electrifications will be on the three-phase system, notably that of the prolongation of the Valtellin line to Milan, which will shortly be taken in hand. It is, however, highly probable that some other lines will be worked single-phase. One of these is the line Turin-Pinerolo-Torre-Pelice, where widely different speeds are necessary, the maximum being 80 km. per hour for 100-ton passenger trains."

In Switzerland the Federal Government appointed some years ago a committee of electrical and railway engineers to report generally on the question of electrifying the Swiss railways. The first report dealt with the amount of power required, the second some standards connected with the future electrical service, whilst a third report dealt with the question of a standard frequency, but on the question whether the single- or the three-phase system is to be chosen the committee has not yet pronounced an opinion. From private conversations I have had with Swiss railway men, I incline to the belief that the decision will be in favour of the single-phase system, especially since, by the use of the Deri type of motor, it has been found possible greatly to simplify and also lighten the accessory equipment. The first test of this motor for traction was made on the three-phase Engelberg railway, one phase only being used. No resistances, auto-transformer, contactors, regulating switches, or controllers of the usual construction are required. The starting and the regulation of the tractive force and speed is effected simply by shifting the brushes. Thus all the driver has to do is to attend to a hand-wheel, the motion of which is transmitted to the brush rockers by positive mechanical gearing.

Winding Engines and Rolling Mills.

Dynamic storage in some such way as first applied by Ilgner to winding engines, and voltage regulation on what may broadly be called the Ward-Leonard system, have made it possible to satisfy the very severe conditions under which winding engines and rolling mills have to work. A good example of modern English practice in direct-current rolling-mill electrification is the plant supplied by the Electric Construction Company, Ltd., of Wolverhampton, to the steel works of Sir Alfred Hickman, Ltd., of Bilston. The makers have given me the following particulars:—The flywheel set consists of a 2000-horse-power direct-current motor, two 28-ton flywheels and two generators capable of giving any voltage between −1000 and +1000 volts. The excitation of the motor is adjusted automatically so as to produce a speed variation of the flywheels between 290 and 350 revolutions per minute. The energy given out when dropping from the higher to the lower speed is 46,000 horse-power seconds. This set supplies power to a cogging and a barring mill. The cogging-mill motor works a 30-inch mill, and when cogging down ingots of 3 tons weight has to develop 4800 horse-power, and for two-second periods once an hour 9600 horse-power. The barring-mill motor works a 24-inch mill, and has to develop 6000 horse-power, and for two-second periods once an hour 12,000 horse-power. The maximum speed is 120 revolutions per minute, and the time occupied in reversing from maximum speed in one direction to that in the other direction is six seconds. As an example of a reversible mill driven by three-phase current I take that supplied by the British Thomson-Houston Company, Ltd., to Messrs. Dorman, Long and Co., Ltd. It is a cogging mill with rolls 28-inch centres, and the normal speed is 70, the maximum speed 90, revolutions per minute. The flywheel set consists of a three-phase 950-horse-power non-synchronous motor, coupled to a 1000-kw. 400-volt direct-current generator and a 30-ton flywheel. The speed limits are 400 and 480 revolutions per minute, and the maximum peripheral speed of the flywheel is 295 feet per second. The mill motor is rated at 1200 horse-power, and has an overload capacity for short periods of 3600 horse-power. The time required for reversing from full speed in one direction to full speed in the other direction is four seconds. The mill deals with 1800-lb. billets 12 inches square, reducing them to 3-inch square bars in fourteen passes. The output is 15 tons per hour.

Electric Steel Furnaces.

In the manufacture of steel from pig and the refining of steel electrically the experimental stage has long been passed, and the practical results obtained are eminently satisfactory. Even where, owing to the price of power, the electric process is no cheaper than the thermic process, the former enables the steel refiner to achieve results with certainty and regularity which under the old methods are hardly attainable at all, or only, so to say, by good luck.

In the furnace electricity is merely used to produce a large amount of heat locally. All furnaces are worked with alternating currents, the heat being produced either in an arc or by the passage of the current through the metal itself. In an arc furnace for a capacity of 2 to 3 tons the average energy required per ton of finished steel is about 1000 kw.-hours when the charge is introduced cold, and about 400 kw.-hours when it is introduced in a molten state.

A drawback inseparable from the employment of electric arcs is the great fluctuation in the load, making it impossible to work an arc furnace from a circuit which supplies other consumers. This difficulty is overcome with the so-called "induction furnace," where the heating is by ohmic resistance. In the latest type of induction furnace the energy required per ton of steel if the charge is introduced in a molten state is 125 kw.-hours for rails and 250 kw.-hours for tool steel.

The electric furnace for steel making and steel refining is now an important accessory in steel works, and thousands of tons of steel are produced annually, both in furnaces of the arc and in those of the induction type.

Fixation of Atmospheric Nitrogen.

Of the many methods devised for fixing atmospheric nitrogen with the object of producing a fertiliser to replace Chili saltpetre, I can only refer to three which have attained considerable importance.

The Birkeland-Eyde process is in use in the Notodden factory. This is fitted with four 7000-kw. generators and thirty-two furnaces, and has a yearly production of 20,000 tons of nitrate of lime, and a second factory on the Rjukan Fall is in course of construction.

The Frank-Caro process is not, strictly speaking, electrical, yet it has only become commercially possible by the aid of electricity. The raw materials for this process are calcium carbide and nitrogen, the former being produced by electricity in the well-known way, and the latter by liquefying air in a Linde machine and subsequent fractional distillation. The carbide is brought to glowing heat in a closed, externally fired retort, and the nitrogen passed through. The reaction is $CaC_2 + N_2 = CaCN_2 + C$.

A new process for the production of nitrous compounds, which is the invention of Messrs. Schoenherr and Heszberger, is being introduced on a large scale in Norway by the Badische Anilin- und Sodafabrik. In this process air is passed through an iron tube in which an alternating-current arc of 5-metre length is maintained under a pressure of 4200 volts. The air enters one end of the tube by a series of tangential holes, and the rotary motion thus produced keeps the arc confined to the axis of the tube. Each arc absorbs 600 horse-power.

Electricity in Agriculture.

The discovery that electrification of the atmosphere immediately above the plant stimulates in certain cases its growth is now being utilised practically under a system worked out by Sir Oliver Lodge, in collaboration with Mr. J. E. Newman and Mr. R. Bomford. A network of galvanised iron wires is stretched over the field to be treated, and suspended 18 feet from the ground from wooden posts and oil insulators. The posts are placed 70 yards apart, so that about one post per acre is required. The network is positively electrified to from 60,000 to 100,000 volts by means of an induction-coil mercury gas break and Lodge rectifying vacuum valves. The induction coil is worked on the primary side by continuous current obtained from an ordinary dynamo. The amount of primary power required per acre is very small, namely, from 10 to 20 watts. The installation is run for five or six months during eight to ten hours each day, and the total expenditure of energy is only about 20 B.O.T. units per annum per acre. Under this treatment the increase in the yield per acre is about 30 per cent., but under certain conditions it may be even more. The system is in use on several farms in this country, on six farms in Germany, and on one farm in Holland.

In the time at my disposal I have only been able to refer to a few of the industries which have benefited by the application of electricity; but when one reflects that nearly every industry in the country has been, or might be, furthered by the use of electricity in one form or another one comes to see that an enormous field of useful work is open to the electrical engineer—not only useful to himself, but even more so to the interests that employ him. How, then, comes it that electrical engineering is not so prosperous as it might be? Some of our members say because we are backward as compared with our foreign competitors. If by that term they mean that our electrical engineering works cannot produce equally good plant as our rivals, I cannot agree. I have frequently visited Continental shops, and, although I am quite willing to admit that excellent work is done there, I am also convinced that British shops can turn out work equally well and generally at a slightly lower prime cost. There is certainly no justification in reproaching the makers of electrical plant with backwardness; and, moreover, it is bad business policy. If, however, the reproach is levelled against the potential users of such plant there is some justification, and also a reason. Our great staple industries are old-established and have been fairly prosperous for generations; those on the Continent are of recent growth, and had to struggle into existence against English competition. To become successful they had to adopt every improvement which science put at their disposal. With them the application of electricity is almost a vital matter; with us only a desirable improvement. Is it, then, to be wondered at if a works manager or owner, who has grown up in the pre-electric days, and has been doing a prosperous business ever since, should be rather slow in embarking in new methods of working which, to his thinking, might entail the possibility of risk and the certainty of greater mental exertion? There are, of course, exceptions, and a good many of them, as witnessed by the great strides which electrical methods applied to our staple industries have already made; but, compared to what the development might be, we must admit that we have as yet only touched the fringe of this vast field. There is progress, but it is not fast enough, and to accelerate it we must educate the potential users of electrical plant. A beginning in this direction has already been made by the managers of electric-light stations. They are educating the householder by local exhibitions and literature that he can understand. On the Continent every large electrical engineering firm has a literary department, the business of which it is to educate possible customers. No sooner is a new winding plant started, or a cotton mill electrically equipped, than well-written, well-printed, and beautifully illustrated leaflets are sent out into the world to tell possible clients of the work done by the firm. Here, such literary departments are the exception; and thus it comes about that we hear so much of the great advances made on the Continent and so little concerning equally good work done here.

Our institution can also do something to accelerate the introduction of electricity into our great industries. It is no doubt very useful if we in our meetings read highly technical papers, and thus educate each other; but this is only part of our work. The other part is to educate the customer, and for this purpose we possess in our organisation of local sections the requisite machinery. By arranging for papers which shall be of interest to the particular industries carried on in the district of each local section, our institution can further the adoption of electricity in these industries, and this will not only be to our own advantage, but even more to the advantage of those whom we serve.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The professorship of biology will be vacant on January 1, 1910, by the resignation of Prof. Bateson as from that date. Candidates for the professorship should communicate with the Vice-Chancellor on or before Monday, January 10. The professor will receive a stipend of 700*l.* a year, with the usual deductions in case he holds a fellowship. It will be the duty of the professor to promote by teaching and research the knowledge of genetics.

The Balfour studentship will be vacant at Christmas, 1909. The names of applicants, together with such information as they may think desirable, should be sent on or before January 15, 1910, to the secretary, Mr. J. W. Clark, Registry of the University, Cambridge.

Dr. Whitehead has been appointed chairman of the examiners for the mathematical tripos, part i., 1910.

Mr. W. B. Hardy has been nominated a manager of the Quick fund from January 1, 1910, to December 31, 1915.

The electors to the Isaac Newton studentships give notice that, in accordance with the regulations, an election to a studentship will be held in the Lent term, 1910. These studentships are for the encouragement of study and research in astronomy (especially gravitational astronomy, but including other branches of astronomy and astronomical physics) and physical optics. The studentship will be tenable for the term of three years from April 15, 1910. The emolument of the student will be 200*l.* per annum, provided that the income of the fund is capable of bearing such charge. Candidates for the studentship should send in their applications to the Vice-Chancellor between January 16 and 26, 1910, together with testimonials and such other evidence as to their qualifications and their proposed course of study or research as they may think fit. Candidates are recommended to send with their applications an account of any work bearing on astronomy or physical optics on which they may have been engaged, and to forward copies of any papers they may have published on these subjects.

The special board for moral science directs attention to the urgent need of more adequate accommodation for the laboratory of experimental psychology. Since 1897, when the lectureship in experimental psychology was first established, this department has been successively housed in various temporary quarters, all totally unfitted for the purpose. At Oxford an excellent laboratory devoted to experimental psychology has recently been erected, presided over by a reader, who is a Cambridge man. This laboratory was built and is maintained at the expense of the University. The board is of opinion that it is essential that a similarly permanent and satisfactory building should be provided without delay in Cambridge if instruction and research in this important new subject are not to cease.

Birmingham.—The Huxley lecture this year is to be delivered on December 1 by Prof. W. Bateson, F.R.S., who has selected "Mendelian Heredity" as the subject of his address.

Mr. Francis Darwin, F.R.S., Prof. Westlake, of Cambridge, and Prof. Holland, of Oxford, have been created Doctors of the University of Brussels. Mr. Darwin has also been made a corresponding member of the Institut National of Geneva.

The Brussels correspondent of the *Times* states that a great scientific meeting was held on November 21 at the Solvay Institute in connection with the Brussels University celebrations. A cheque for 160,000*l.* was presented on November 19 by the friends of the University.

Dr. D. Waterston has been appointed professor of anatomy in King's College, London, in succession to Prof. Peter Thompson, appointed professor of anatomy in the Birmingham University. Dr. G. C. Low has been elected lecturer in parasitology and medical entomology.

The new botanical laboratories at University College, London, will be opened on Friday, December 17, by Dr. D. H. Scott, F.R.S. The Vice-Chancellor (Prof. M. J. M. Hill, F.R.S.) will preside. Applications for tickets of admission should be made to the secretary, University College, London, W.C.

At a meeting of the East London College committee on November 16 a subcommittee was constituted to administer the fund for the encouragement of research work at the college, upon which Mr. H. F. Donaldson, C.B., Dr. H. A. Miers, F.R.S. (principal of the University of London), and Sir William White, K.C.B., F.R.S., were asked to serve.

A copy of the October issue of the *Battersea Polytechnic Magazine* has been received. The periodical provides an interesting record of the doings of the various societies and clubs in connection with the institution, as well as readable articles by members of the staff and students. Great prominence is given to the work of the day section of the Engineering Society; the issue of the magazine before us, for example, contains full descriptive accounts of four visits to important engineering undertakings, in addition to complete particulars of the annual meeting of the society.

The School Board of Hartford, Connecticut, has decided to establish a "tent school" for children from homes where there is tuberculosis, and for children who suffer from anæmia or curvature of the spine. The tents will be put up on some vacant ground in the neighbourhood of one of the city's school buildings. Accommodation will be provided for sixty or more children, who will spend about seven hours a day in the tents. Books and furniture will be supplied by the School Board, but the Hartford Society for the Prevention of Tuberculosis will furnish meals and the especially warm clothing that will be needed for such an experiment during the winter.

Dr. Richard Arthur, president of the Immigration League of Australasia, points out in a circular letter that the Government agricultural colleges in Australia offer exceptional advantages in the way of a scientific and practical education in the various forms of agriculture, stock-breeding, dairying, and fruit-growing. He has been able to make arrangements for the reception of students from the United Kingdom at them, and informs us that any lad going to Australia can now be guaranteed entrance at one or other of these institutions. The course is a two-year one, and the fees are exceedingly moderate, ranging from 18*l.* to 30*l.* a year, which sum includes board and lodging.

We learn from *Science* that by the will of the late Mr. John S. Kennedy, banker, of New York City, who died last October in his eightieth year, bequests are made for public purposes amounting to nearly 6,000,000*l.* A bequest of 445,000*l.* is made to Columbia University; another of 300,000*l.* to Robert College, Constantinople; and a bequest of 150,000*l.* to New York University. Gifts of 20,000*l.* are made to the University of Glasgow, Yale University, Amherst College, Williams College, Dartmouth College, Bowdoin College, Hamilton College, the Protestant College at Beirut, the Tuskegee Institute, and Hampden Institute; and of 10,000*l.* to Lafayette College, Oberlin College, Wellesley College, Barnard College (Columbia University), Teachers College (Columbia University), Elmira College, Northfield Seminary, Berea College, Mt. Hermon Boys' School, and Anatolia College, Turkey. Bequests of 5000*l.* are made to Lake Forest University and Center College.

A union has recently been formed by graduates of the University of London to promote the Parliamentary enfranchisement of women on the same terms as men. Since 1878 the University of London has admitted women as candidates for all degrees, honours, and prizes on precisely the same terms as men, and at the present day in all university affairs men and women are accorded the same electoral and other rights, and acquire them through identical qualifications. Graduates of a certain standing are entitled to become members of Convocation, and the register of Convocation would constitute the Parliamentary electoral roll were it not for the condition imposed by Act of Parliament that a Parliamentary voter must be of the male sex. About one-sixth of the members of Convocation are thus deprived of any share in the choice of the representative of their university in Parliament. That such exclusion of an intellectual section of the nation from representation in its councils is contrary to public policy cannot be denied. The university qualification for the vote is a purely intellectual one, and those who do not recognise its sufficiency in the case of one sex would have a difficult task to maintain the right of the other to the privilege attaching to that qualification. All graduates of the University of London—both men and women—who are in sympathy with the objects of the union are urged to join it. Particulars and forms of membership can be obtained from Miss Jessie W. Scott, hon. sec. London Graduates' Union for Woman Suffrage, 114A Harley Street.

The prospects in the matter of the inauguration of a Teachers' Registration Council are much brighter as a result of a conference held on November 13, when representatives of all the important teachers' associations met together, under the presidency of Sir Herbert Cozens-Hardy, Master of the Rolls, to discuss the whole question of registration and to pass resolutions expressing the general feeling of teachers throughout the country. The proposals agreed upon include the establishment of a council on which elementary, secondary, and technical education are represented equally, each by nine representatives, and associations of teachers not included under these three heads by three representatives. Technological education is given a very wide interpretation in the proposed scheme, and includes the work done in technical schools, schools of art, and by teachers of music, of commercial subjects and physical education in its various branches. There were few points on which the meeting had difficulty in coming to practically unanimous conclusions, and armed with the resolutions now adopted the representatives of the conference should have little trouble in convincing the Board of Education that the time has arrived when the provisions included in Education Acts, which long since came into force, for the establishment of a Teachers' Registration Council should be put into force. The work of education is, from the national point of view, of prime importance, and any procedure deserves encouragement which will improve the status of the teaching profession.

Sir John Hewett opened the new laboratories and workshops at Thomason College, Roorkee, at the end of October last, and the address he gave on that occasion is printed in the *Pioneer Mail* of November 5. The speech was the first statement of the general policy accepted by the provincial Government for the development of technical and industrial education. The encouragement of education in applied science was taken up by Sir John Hewett at an early stage of his administration, his first step being the promotion of a technical conference. The proposals of the conference included the provision of industrial and trade schools at important centres and the improvement of the existing industrial school at Lucknow. These were to provide for the lower stages of industrial training. Our contemporary states that this scheme has been adopted by the Government, and is being given effect to as funds are available. Eventually these establishments may be expected to provide a regular supply of trained artisans and mechanics able to adapt themselves readily to western processes. The proposals of the conference referred also to the creation of a technological institute. This institute was to have two branches—at Roorkee and Cawnpore respectively; it was intended that Roorkee should deal only with industries mainly dependent on engineering, while Cawnpore provided for those dependent on chemistry. The proposals allotted 2 lakhs capital expenditure with Rs. 88,000 annually to Roorkee, and 8 lakhs capital with 2½ lakhs annually to Cawnpore. Sir John Hewett said in his speech that the Cawnpore part of the scheme has been deferred, but that a commencement will be made at once with the development of a technological institute at Roorkee. Thomason College is to have the difficult task of working out the lines on which the functions of a technological institute can be carried out in India.

SOCIETIES AND ACADEMIES.

London.

Geological Society, November 3.—Prof. W. J. Sollas, F.R.S., president, in the chair.—S. S. **Buckman**: Certain Jurassic (Lias-Oolite) strata of south Dorset, and their correlation. Descriptions of certain strata (Lower Bathonian to Pliensbachian) on the Dorset coast. Comparison is made with similar strata inland. The strata described are classified according to the scheme introduced for these strata in 1893. The strata are arranged among thirty-six zonal (hemeral) divisions. The Upper Lias part of the junction-bed of Down Cliffs, Chideock, is a very condensed, imperfect epitome in 20 inches of about 80 feet of strata on the Yorkshire coast. Between the *bifrons*-layer and the *striatulus*-layer of the junction-bed there is occasionally a 2-inch layer, which is all that represents some 250 feet of deposit in the Cotteswolds. The Upper Tearcian makes a great showing at Burton Bradstock and Down Cliffs as the Down Cliffs Clay and Bridport Sands. The sequence of *aalensis*-strata above *moorei*-beds is demonstrated at Chideock Quarry Hill, in the upper part of the Bridport Sands. The Inferior Oolite strata of Burton and Chideock are not counterparts of one another; they supplement each other to a certain extent. Mr. Thompson's zonal scheme for the Upper Lias is considered.—S. S. **Buckman**: Certain Jurassic ("Inferior Oolite") Ammonites and Brachiopoda. The paper describes certain species of Ammonites and Brachiopoda which are important for the identification, the correlation, or the dating of Inferior Oolite deposits, and certain other notable species which, having frequently attracted attention in the field, require naming in the interest of future workers.—Dr. W. F. **Hume**: The granite-ridges of Kharga Oasis: intrusive or tectonic? The author quotes the records given by Mr. Beadnell in his paper published in February, 1909, and although in agreement with the facts there stated, differs with regard to the interpretation of those facts. Whereas Mr. Beadnell regards the granite as intrusive, on account of the high dip of the sedimentaries, and the changes which they exhibit as regards colour and hardness, near the granite, the author considers that the dips are due to fold-movements almost at right angles to one another, since they lie on the same line as the crater-like basins, the rims of which are formed of the compact and steeply dipping limestones of the Lower Eocene, and he adduces as further evidence the fact that dykes and quartz-veins penetrating the crystalline rocks cease abruptly at the edge of the sandstone.—Dr. W. F. **Hume**: The Cretaceous and Eocene strata of Egypt. The fossiliferous Cretaceous strata are divided into three series:—(1) A northern Antonian type, marked by Cenomanian species, including typical Turonian strata. (2) A central Egyptian or Hammama type, Cenomanian strata being absent, Campanian marked by abundance of *Ostrea villei* and *Trigonarca multidentata*, and phosphatic beds; the Danian portion having an eastern facies, in which Pecten marls are a characteristic feature, and a western chalky limestone indicating a close affinity with the white chalk of northern Europe. (3) A southern or Dungul type, having close affinities with (2), but in the Campanian the phosphatic beds are inconspicuous, and the fauna consists of a group of specialised sea-urchins and of gastropods, among which Turritellæ are very prominent. The uniformity of the Lower Eocene throughout Egypt is emphasised, its triple subdivision being recognisable over vast areas. In the Middle Eocene this uniformity is replaced by differentiation. Five zones have been recognised in the lower division, while in the Upper Moqattam the Turritella-beds and the strata rich in *Carolia placunoides* and *Plicatula polymorpha* are of zonal importance. The Lower Moqattam is considered as beginning with the *Nummulites gizehensis* zone and closing with the Gistortia-bed. The relation between the Cretaceous and Eocene beds is discussed. Palæontologically, great groups such as the Ammonites, still abundant in the Upper Cretaceous, disappear in the Eocene, and are replaced by the characteristic nummulinid Foraminifera. Both periods bear a resemblance to each other in the dominance of oysters and sea-urchins. A notable feature is the rarity of Brachiopoda in Egypt throughout both periods, nor have belemnites been recorded from the Egyptian Cretaceous. Among post-Eocene formations the calcareous grits are shown to have a wide extension, but in the desert they differ in character from the mammal-yielding beds of the Fayûm. The Cretaceous period in Egypt was one, in the main, marked by the gain of sea over land, the Eocene was one of rest, while at the close of the Eocene and during the Oligocene the approach of a continental phase is clearly indicated.

Linnean Society, November 4.—Dr. D. H. Scott, F.R.S., president, in the chair.—Cecil **Carus-Wilson**: Natural inclusion of stones in woody tissue. About twenty-three years ago a gravel-pit was started in the valley-gravels occurring some three miles from Faversham, in Kent. Part of a wood covered the deposit; as the work progressed oak trees were felled, and the stumps and roots dislodged. The gravel consists of subangular, water-worn flints and occasional blocks of Sarsen-stone, the whole being mixed with flint grit and quartzose sand. The roots and stumps were distributed as the gravel in which they were embedded was removed. The work of excavating ceased about ten years ago, so the roots still remaining have been exposed for that length of time, the others having been cut up for fuel. Most of those now found were left intact because of the stones enclosed in the wood. Not only did these resist the work of saw and axe, but when burnt they burst asunder with force, becoming a source of danger. The stones are actually embedded in the solid oak. The tissue of the wood appears to have grown around the stones and enveloped them, indicating that the process was carried on under conditions of pressure. There are dozens of stones embedded in some of these roots, so that the substance may be described as "a conglomerate formed of flints enclosed in a woody matrix." In one specimen no fewer than sixty-seven flints were counted, the largest being several pounds in weight, and there are innumerable empty cavities showing where others existed before the shrinkage of the wood after exposure. Odd stones have been occasionally seen thus embedded in the trunks of trees. In Norton Churchyard, a few miles from Faversham, are three old yew trees, and in two of them flints and fragments of tiles have been seen embedded in the wood of the trunk 7 feet above the ground. In Molash Churchyard, six or seven miles south of Faversham, there are six very old and large yews. Some of these have flints embedded in their trunks 7 feet or 8 feet above the ground. The examples first described are unique, and if trees can enclose stones in such quantities, and retain them within their substance so tenaciously, we have transporting agents capable, under certain conditions, of distributing terrigenous material over sea-beds to an extent not hitherto appreciated.—Dr. A. B. **Rendle**: Specimen of heather (*Erica cinerea*) found near Axminster in which the flowers were replaced by dark red leaf-buds of about the same size as the flowers. The red leaf-buds, which occupy the position of flowers, consist each of short, strongly ascending leaves arranged in superposed whorls of four; the four lines have often a spiral twist in the upper part of the bud. The leaf-arrangement resembles that of the flower, not of the foliage leaves. The leaves of these special buds differ in form from the foliage leaves in that they are upwardly concave with a bluntly keeled back. They are thirty-two or more in number, and thus considerably outnumber the parts of a typical flower (twenty-four, including bracteoles). The tip of the bud was always damaged, but in many a shrivelled pistil was present, and sometimes below this semi-foliaceous stamens were found. The specimen is of interest as resembling a teratological form of *Erica cinerea* described by Maxime Cornu in 1879.—Prof. H. H. W. **Pearson**: Types of the vegetation of Bushmanland, Namaqualand, Damaraland, and South Angola (a preliminary report of the Percy Sladen Memorial Expedition in South-west Africa, 1908–9). The floras of the regions named in the title are distinctly related if the vegetation found on the Huilla plateau in South Angola be excluded. Otherwise the differences that are observed are to be accounted for mainly as a result of differences of (1) elevation; (2) atmospheric humidity; (3) depth at which permanent supplies of underground water are available; (4) geographical position. In all the rainfall is scanty and inconstant, and there is a prolonged drought in the winter season. Near the coast, in some places up to elevations as great as 2700 feet, the total annual rainfall is never more than a few millimetres, and frequently fails altogether. The affinities of these floras are with those of the South Central African highlands. In South Angola many species are derived undoubtedly from the coast and Montane regions of West Tropical Africa. Throughout, the vegetation is xerophytic in character, and is marked either by a short period of duration or by the possession of those structural peculiarities which are found in dry climate perennials. Of these, hairiness is not a conspicuous feature; except in Lower Namaqualand, succulence is not common. A round, bushy habit is marked throughout. The root system is deep; the leaves are simple and of small size, and with a strongly developed cuticle. The formations and associations indicated are predominant by reason either of their great extent or of striking peculiarities of the plants composing them. They are arranged in the main geographically from south to north.

Zoological Society, November 9.—Dr. S. F. Harmer, F.R.S., vice-president, in the chair.—Sir H. H. **Howorth**: Some living shells, their recent biology, and the light they throw on the latest physical changes in the earth, i., *Mya arenaria*. The author stated that the *Mya arenaria* or clam is widely distributed in the North Boreal, European, and North American seas, and claimed to prove that it is a recent migrant into the former, and has probably not been there more than 300 years. The notion that it is an Arctic shell is a mistake. In the Arctic lists *Mya truncata*, var. *oblonga*, has been mistaken for it, and the glacial character of the beds in which it has occurred, which has been postulated from its occurrence there, has accordingly been a wrong inference. Brögger has argued that it migrated from America. It was abundant in the Crag seas, and occurs in derivative fragments in the Drift-beds, but it does not occur in the estuarine deposits or raised beaches, proving that after the period of the Crag it became extinct in Europe, and has since been re-introduced. He regarded the cause of its extinction as a mystery, since the group of estuarine shells with which it is found has lived continuously in Europe since later Crag times.—C. Tate **Regan**: The Asiatic fishes of the family Anabantidæ (including the Osphromenidæ). The author remarked that the order Labyrinthici was an isolated and terminal group, probably derived from a cyprinodontoid stock, and that it comprised two suborders, Ophiocephaloidei and Anabantoidei, the latter including the families Anabantidæ and Luciocephalidæ. The Indian element in the fresh-water fish-fauna of Celebes, including two labyrinthic fishes, was shown to consist of (1) species which had travelled by sea, and (2) species which had probably been introduced by man. The great importance of Wallace's line for fresh-water fishes was thus vindicated. The Asiatic genera and species of Anabantidæ were described, including several new forms of Betta and Trichopodus, and the Asiatic genus Anabas was shown to differ markedly from the African Ctenopoma and Spirobranchus.—J. Lewis **Bonhote**: Some mammals brought home from Egypt. The paper dealt with about twenty-eight species, chiefly small rodents, and the main points of interest were the recognition of *Procavia burtoni*, the Egyptian hyrax, as a valid species, the re-discovery of *Acomys russatus*, hitherto only known from Palestine, and the description of a small species of Dipodillus, the last two species having been taken on the Mokattam Hills within three miles of Cairo.

Mathematical Society, November 11.—Sir W. D. Niven, president, in the chair.—G. H. **Hardy**: (1) The ordinal relations of the terms of a convergent sequence; (2) the application to Dirichlet's series of Borel's exponential method of summation; (3) theorems relating to the summability and convergence of slowly oscillating series.—Prof. W. **Esson**: Notes on synthetic geometry.—H. **Bateman**: Kummer's quartic surface as a wave surface.—Prof. H. S. **Carslaw**: The Green's function in a wedge and other problems in the conduction of heat.—J. L. S. **Hatton**: The envelope of a line cut harmonically by two conics.—Rev. F. H. **Jackson**: A class of q-hypergeometric series.—Informal communications were made as follows:—Dr. E. W. **Hobson**: An extension of Abel's theorem concerning the sums of series at points on the circle of convergence to oscillatory series.—Prof. A. E. H. **Love**: The effect of the earth's rotation upon the observed values of the lunar disturbance of gravity.

Cambridge.

Philosophical Society, October 25.—Dr. Hobson, vice-president, in the chair.—A. A. **Robb**: Discussion of a difference equation relating to the tension of overhead wires supported by equidistant poles.—F. G. **Sinclair**: Note on the abnormal pair of appendages in Lithobius.—J. E. **Littlewood**: A class of integral functions.—J. A. **Crowther**: The scattering of the β rays from radium by air.—R. **Whiddington**: Note on the electrical behaviour of fluorescing iodine vapour. The note describes an experiment showing that iodine vapour is un-ionised when brilliantly fluorescing under the action of the arc light.—Rev. H. J. **Sharpe**: The reflection of sound at a paraboloid.—G. W. C. **Kaye**: The emission of Röntgen rays from thin metallic sheets. Thin metal leaf antikathodes were subjected to bombardment by kathode rays, and the (emergent) X-rays proceeding from the remote side of the leaf were compared with those which left on the near side (incident). In general, the emergent Röntgen radiation in such cases exceeds the incident in intensity, markedly so in the case of aluminium. The ratio of the emergent intensity to the incident increases with the speed of the kathode rays employed. As the thickness of the metal leaf is increased, the emergent intensity increases to a maximum and then dies away, the incident intensity meanwhile gradually increasing to a constant value.—F. **Horton**: The emission of positive rays from heated phosphorus compounds.

November 8.—Prof. Bateson, F.R.S., president, in the chair.—N. R. **Campbell**: Discontinuities in light emission. An account is given of an attempt to test the theories of Sir J. J. Thomson and of Planck as to the atomic nature of radiation by means of observations on the fluctuations in the intensity of a source of light. The experiments are similar in nature to those of Meyer and Regener, based on the theory of von Schweidler, on the fluctuations of an ionisation current due to the α rays of radium. The theory and the methods of the experiments are discussed at length, and also the nature and cause of an unexpected difficulty which has prevented, up to the present time, the attainment of definite results; but it is hoped that such results may be reached in the near future.—J. A. **Orange**: The shape of beams of canal rays. An appendix to a paper previously communicated to the society. In that paper it was suggested that the component rays in a beam of canal rays are straight, the curved boundaries of the beam being envelopes merely. This appendix describes one or two simple experiments which support that view.—H. **Bateman**: The determination of solutions of the equation of wave motion which involve an arbitrary function of three variables which satisfies a partial differential equation.—H. J. **Priestley**: The oscillations of superposed fluids.—L. B. **Turner**: The stresses in a thick hollow cylinder subjected to internal pressure.—Sir J. J. **Thomson**: The theory of the motion of a charged particle through a gas. It is pointed out in this paper that, in consequence of the "persistence of velocities," which is especially marked when the mass of an ion is much greater than that of a molecule of the gas through which the ion is moving, methods founded on the conception of the free path are not suited for the calculation of the velocities of the ions. If we suppose that the operative forces acting between the ions are such as exist between a charged body and a conducting sphere, the force between the ions and the molecules would, except close to the molecules, be proportional to the inverse fifth power of the distance, and we can apply Maxwell's results to this case, making the slight alterations which are necessary when the force is an attraction instead of a repulsion, as in Maxwell's investigation. The expressions deduced in this way for the mobility are such that, considered as a function of M, the mass of the ion, and m, the mass of a molecule of the gas, the mobility varies as $\left\{\frac{M+m}{M}\right\}^{\frac{1}{2}}$, and thus, when M is large compared with m, varies very slowly with the mass of the ion. The diffusion of the emanations of radioactive substances through air or other gases would, since the molecules of the emanation carry electrical charges, follow the same law, so that the rate of diffusion of the emanation would only vary very slowly with the atomic weight; thus we cannot attach much importance to determinations of the atomic weight of the emanation made by observing their rate of diffusion through other gases.

MANCHESTER.

Literary and Philosophical Society, November 2.—Mr. Francis Jones, president, in the chair.—T. G. B. **Osborn**: A note on the staminal mechanism of *Passiflora coerulea*. The paper contained a record of observations made during the summer of this year on *Passiflora coerulea*, and directed attention to three staminal movements which occur in the order in which they are given below, viz.:—(1) A radial movement of the anthers on the filament of 180°, which occurs as soon as the flower opens. (2) A second movement of the anther through 90° into a plane at right angles to the first, *i.e.* into the tangential plane, in which position a special mechanism is called into play to retain it there. (3) The radial movement, in two stages, of the stamen as a whole, so as to bring it from an erect to a drooping position, the first stage of this movement being in part concurrent with (2), and coextensive with the first stage of anthesis.—D. M. S. **Watson**: A preliminary note on two new genera of Upper Liassic Plesiosaurs. The Manchester Museum contains two important skeletons of *Plesiosaurus homalospondylus*, Owen, which show that the pectoral girdle does not conform to the type of that of Plesiosaurus, but is elasmosaurian, resembling that of Cryptocleidus. The coracoids are narrow; the scapulæ meet in the middle line and pass back as a bar to join the coracoids. The clavicular arch is reduced, lying on the visceral surface of the anterior plates of the scapulæ. There is no interclavicle. A new genus, Microcleidus, is founded for the species. Another skeleton, lacking the head, also in the Manchester Museum, is made the type of the new genus and species *Sthenarosaurus dawkinsi*. The genus is remarkable for the smallness of the coracoids and the strong clavicular arch, which resembles that of Thaumatosaurus, as determined by Lydekker, but has a posterior process in the centre.

November 16.—Mr. Francis Jones, president, in the chair.—C. E. **Stromeyer**: Relative periods of revolution of planets and satellites. The author pointed out that, if the solar system has been built up out of meteorites, certain relations as regards periods of revolution should exist both amongst the planets and their satellites. The periods, not only of the planets, but also of their satellites, should be expected to stand in the ratios 1, 2, 4, 8, &c., or 1, 3/2, 2, 3, 4, &c. The first of these series is well represented by Jupiter's satellites, I., II., and III. of which stand in the exact ratio of 4, 8, 16; V. has a period of 1·1, IV. has a period of 37·8 instead of 32, and VI. and VII. combined have a period of 576, or little more than 512, which would be the tenth term of the series. The outermost satellite, the exact period of which has not yet been determined, should, if the above rule holds good, have a period of twice 260 days, say one and a half years. Saturn's satellites agree with the second series, which includes thirds. The mean periods of the several pairs are 1, 2, 3·96, —, 16·5, —, 68·1.—F. **Nicholson**: Some early correspondence between Mrs. Hemans and Mr. Matthew Nicholson, a former member of the society.

PARIS.

Academy of Sciences, November 15.—M. Bouchard in the chair.—G. **Darboux**: Congruences of curves.—M. **Gouy**: The vapour pressure of an electrified liquid. The total effect, at least for liquids having a high specific inductive capacity, is for an electric field to increase the vapour pressure. The dielectric polarisation, when the field is normal to the surface, produces an increase in the vapour pressure; the increase of the ions in the surface layer of the electrolyte diminishes the vapour pressure, and the net result is the difference of these two effects.—M. **de Forcrand**: The acid carbonates of the alkalies.—Édouard **Heckel**: The influence of anæsthetics and frost on plants containing coumarin. Plasmolysis is produced by the action of chloroform, ether, or by cold, the coumarin being immediately given off.—Édouard **Heckel**: Fixation of the cultural bud-formation of *Solanum maglia*.—M. **Idrac**: Ocular and photographic observations of the planet Mars. An account of observations made at the Meudon Observatory with the large double telescope during the recent opposition of Mars. In some instances details were shown on the photographs which could not be observed by simultaneous eye observations.—E. M. **Antoniadi**: Observations of the planet Mars made at the Observatory of Meudon. A map of the planet, on Mercator's projection, is given, summarising observations made between September 20 and November 9.—A. de la Baume **Pluvinel** and F. **Baldet**: The photography of the planet Mars. An account of work done with the new equatorial at the astronomical station on the Pic du Midi.—N. E. **Norlund**: Equations of finite differences.—G. A. **Miller**: Groups produced by two operators, each of which transforms the square of the other into its inverse.—Albert **Grumbach**: Contact electrification. A study of the electromotive forces produced by the filtration of solutions of potassium chloride, with and without an added non-electrolyte (phenol).—Vasilesco **Karpen**: Telephony at great distances.—André **Léaute**: The destructive effects of oscillating discharges of high frequency.—Gargam **de Moncetz**: A formula for sensitising plates for the extreme red, commencing with the infra-red. The solutions given, used on silver iodobromide plates, enable lines up to the calcium line λ 860 to be photographed.—Paul **Gaubert**: A new highly fluorescent substance derived from physostigmine. Physostigmine in aqueous solution is allowed to stand for several months until it has acquired a deep blue colour, and to this phthalic acid is added. The substance produced forms deep blue crystals, which in solution are intensely fluorescent.—W. **Broniewski**: The electrical properties of the aluminium-copper alloys. Twenty alloys of aluminium and copper were prepared. The measurements made on these included the electrical conductivity at 0° C., the temperature coefficient of the resistance, the electromotive force against carbon in a solution of ammonium chloride, and the thermoelectric power. The results are given both in tabular and graphical form. In addition to the definite compounds of aluminium and copper already known, the existence of Al_2Cu_3 has been brought out by these experiments.—Georges **Meslin**: The magnetic properties of liquids constituted by siderose. Aniline or carbon bisulphide containing powdered siderose in suspension exhibit the phenomenon of magnetic dichroïsm to an extent much greater than with any substances previously examined.—Abel **Buguet**: The cryoscopy of organic mixtures and addition compounds. An account of the cryoscopic study of mixtures of acenaphthene and phenanthrene with two nitrotoluenes.—H. **Baubigny**: The action of heat and light on silver sulphite and the double alkaline sulphites. The determination of the yield of dithionic acid.—V. **Auger**: The mixed halogen stannic compounds. The bromiodide $SnBr_2I_2$ was submitted to a series of slow crystallisations, and the ratio of iodine to bromine found to vary. The study of the cooling curve of the supposed $SnBr_2I_2$ showed that this also behaved as a mixture.—P. J. **Tarbouriech**: The dehydration of oxycyclohexyldimethylcarbinol.—M. **Deprat**: The eruptive and metamorphic formations of Tonkin, and on the frequency of laminated types.—F. **Grandjean**: The optical study of the absorption of heavy vapours by certain zeolites. The substances absorbed by the crystal of zeolite affect the optical properties of the crystal to a marked extent. The optical properties found are never intermediary between those of the crystal and those of the body absorbed.—Fernand **Guéguen**: The existence of sclerotes in *Mucor sphaerosporus*.—R. **Anthony** and W. B. **Pietkiewicz**: New experiments on the *rôle* of crotaphytic muscle (temporal) on the morphological constitution of the skull and face.—Louis **Lapicque**: The theory of electrical stimulation: a hydraulic analogy.—M. **Baudran**: Artificial media capable of attenuating or strengthening the virulence of Koch's bacillus. The formulæ of the two media differ only in the use of iron in the one and manganese in the other. The one containing iron causes a marked attenuation in the virulence of the bacilli grown in it; the replacement of the iron by manganese, on the other hand, has the exactly contrary effect.—MM. **Trillat** and **Sauton**: The action of putrid gases on micro-organisms. The putrid gases arising from the decomposition of animal extracts were allowed to act on yeast, parallel cultures of the same yeast without the addition of such gases being made at the same time. The effect on the yeast was measured by the alcohol produced. Both increases and decreases in the fermentative action were observed, the effect depending on the proportion of gas present.—Alfred **Angot**: The earthquake of November 10, 1909. Details of the traces of the seismographs at Parc Saint-Maur Observatory. The epicentre was calculated to be at a distance of 8700 kilometres.—M. **Audouin**: Observations made in the course of the Tilho expedition. —M. **de Beauchamp**: The working of the apparatus for the protection of the Vienne district against hail and thunderstorms during the year 1909. The protection during the year has been very satisfactory, and the system is to be further extended.—A. **Gruvel**: *Résumé* of some scientific observations made on the coasts of Mauritania (N. Africa) from 1905 to 1909.

DIARY OF SOCIETIES.

THURSDAY, November 25.

Royal Society, at 4.30.—On the Change in Hue of Spectrum Colours by Dilution with White Light: Sir William de W. Abney, K.C.B., F.R.S.—On the Nature of the Hydrogen Flocculi and their Structure at Different Levels in the Solar Atmosphere: Prof. G. E. Hale, For.Mem.R.S., and F. Ellerman.—The Boiling Point of Sulphur corrected by Reference to New Observations on the Absolute Expansion of Mercury: Prof. H. L. Callendar, F.R.S., and H. Moss.—(1) On the Refraction and Dispersion of Neon; (2) On the Refraction and Dispersion of Air, Oxygen, Hydrogen, and Nitrogen; (3) On the Refraction and Dispersion of Sulphur Dioxide and Hydrogen Sulphide, and their Relation to those of their Constituents: C. Cuthbertson and M. Cuthbertson.—On Flapping Flight: Prof. M. F. Fitzgerald.—The Crystalline Structure of Iron at High Temperatures: W. Rosenhain and J. C. W. Humfrey.—The Relation of Thallium to the Alkali Metals: a Study of Thallium-zinc Sulphate and Selenate: Dr. A. E. H. Tutton, F.R.S.—On the Nature of the Diffraction Figures due to the Heliometer: P. F. Everitt.—The Motional Effects of the Maxwell Æther-Stress: E. Cunningham.—The Aberrations of a Symmetrical Optical Instrument: Dr. H. C. Pocklington, F.R.S.—The Spectrum of Radium Emanation: H. E. Watson.—The Electric Conductivity and Density of Solutions of Hydrogen Fluoride: Prof. E. G. Hill and Dr. A. P. Sirkar.—Sleeping Sickness in Uganda. Duration of the Infectivity of the *Glossina palpalis* after the Removal of the Lake-shore Population: Colonel Sir David Bruce, C.B., F.R.S., Captains A. E. Hamerton and H. R. Bateman, R.A.M.C., and Captain F. P. Mackie, I.M.S.

Institution of Electrical Engineers, at 8.—The Present Aspects of Electric Lighting: H. W. Handcock and A. H. Dykes.

FRIDAY, November 26.

Physical Society, at 5.—The Effective Resistance and Inductance of a Helical Coil: Dr. J. W. Nicholson.—Ductile Materials under Combined Stress: W. A. Scoble.—The Recoil of Radium C from Radium B: Dr. W. Makower and Dr. Sidney Russ.—The Sun's Motion with Respect to the Æther: Dr. C. V. Burton.

MONDAY, November 29.

Royal Society of Arts, at 8.—Aëronautics: C. C. Turner.

Institute of Actuaries, at 5.—American Railway Securities as Investments for Insurance Companies: H. Ansell.

TUESDAY, November 30.

Royal Society of Arts, at 4.30.—Agricultural Development in Nyasaland: S. Simpson.

Royal Anthropological Institute, at 8.15.—The Pit Dwellings at Holderness: Canon Greenwell, F.R.S., and Rev. R. A. Gatty.

Faraday Society, at 8.—On the Electro-analytical Determination of Lead as Peroxide: Dr. H. J. S. Sand.—The Calorimetrical Analysis of Hydrated Salt: Prof. F. G. Donnan and Dr. G. D. Hope.—(1) On the Influence of Dissolved Gases on the Electrode Potential in the System Silver-Silver Acetate, aq.; (2) Contributions to the Study of Ionisation in Aqueous Solutions of Lead Acetate and Cadmium Acetate: A. Jacques.

Institution of Civil Engineers, at 8.—*Further discussion*: The Single-phase Electrification of the Heysham, Morecambe and Lancaster Branch of the Midland Railway: J. Dalziel and J. Sayers.—The Equipment and Working-results of the Mersey Railway under Steam and under Electric Traction: J. Shaw.—The Effect of Electrical Operation on the Permanent-way Maintenance of Railways, as Illustrated on the Tynemouth Branches of the North-Eastern Railway: Dr. C. A. Harrison.

WEDNESDAY, December 1.

Royal Society of Arts, at 8.—Improvements in Resilient Wheels for Vehicles: Hon. R. C. Parsons.

Society of Public Analysts, at 8.—The Composition of Cream: R. R. Tatlock and R. T. Thomson.—Analyses of Vulcanised Rubber Goods: Clayton Beadle and Henry P. Stevens.—On the Gravimetric Estimation of Nickel in Nickel Steel: E. L. Rhead.—Notes on the Milk Supply of Two Large Towns: F. W. F. Arnaud and Edward Russell.

Geological Society, at 8.—The Tremadoc Slates and Associated Rocks of South-east Carnarvonshire: W. G. Fearnsides.—On some Small Trilobites from the Cambrian Rocks of Comley, Shropshire: E. S. Cobbold.—(1) The Rock of Pulau Ubin and Pulau Nanas, Singapore; (2) The Tourmaline-Corundum Rocks of Kinta, Federated Malay States: J. B. Scrivenor.

Entomological Society, at 8.—Discussion on *Agriades coridon* and *A. thetis* (*bellargus*), opened by Mr. J. W. Tutt.

THURSDAY, December 2.

Royal Society, at 4.30.

Röntgen Society, at 8.15.—Some Effects of Electrical Discharges on Photographic Plates: Prof. A. W. Porter.

Linnean Society, at 8.—Nudibranchs from the Indian Ocean: Sir Chas. Eliot, K.C.M.G.—Trichoptera von Mr. Hugh Scott, auf den Seychellen gesammelt: Dr. Georg Ulmer.—Report on the Brachiopoda obtained from the Indian Ocean by the *Sealark* Expedition, 1905: Dr. W. H. Dall.—Narrative of the *Sealark* Expedition, Part III.: Prof. J. Stanley Gardiner, F.R.S., and others.

FRIDAY, December 3.

Institution of Civil Engineers, at 8.—The Design of Generating Stations: G. Ingram.

JOHN DEE.

John Dee (1527–1608). By Charlotte Fell Smith. Pp. xvi+342. (London: Constable and Co., Ltd., 1909.) Price 10*s*. 6*d*. net.

IN the personal history of learning there is probably no more interesting or more perplexing figure than the subject of this book. The story of John Dee reads more like a romance by Sue or a *feuilleton* by the elder Dumas than as a sober, veracious narrative of an actual human career. The achievements of the man, his learning, the range of his knowledge, his aberrations, his vicissitudes of good and evil fortune—mainly evil—taken together, make up a tale which has hardly a parallel in biographical literature, certainly not in the biography of science.

There is a time-honoured adage that a man is to be judged by the company he keeps. John Dee certainly mixed in very questionable company during one period of his extraordinary career, and his memory has greatly suffered from that circumstance. Although he enjoyed the patronage, and to some extent the protection, of the great—mainly from motives of self-interest—his contemporaries for the most part looked askance at his performances, and his life in consequence became a continuous and prolonged struggle with prejudice, misrepresentation, and slander.

Miss Fell Smith may be congratulated unreservedly on her work. Even in this age, which has witnessed many attempts to reverse the adverse judgment of a man's fellows, it needed some courage to try to rehabilitate John Dee in the good opinion of posterity. But, by treating her subject in the spirit of science, that is, by patiently investigating the facts, carefully sifting and weighing the evidence, and skilfully unravelling the tangled web of truth and fiction which has hitherto enveloped his history, his latest biographer has for the first time succeeded in laying bare his true character, and in revealing the hidden springs and motives of his actions. In the record she has put together, Miss Fell Smith has elaborated her testimony and presented the case for the panel, as the Scotch say, with no ordinary literary ability, and the dispassionate reader must admit that she has succeeded in clearing the old philosopher's memory from the charges of deceit, dissimulation, and knavery which lay heavy on it.

In reality, John Dee was a man born out of due season. His age was not ready for him. In the times of the Tudors there was no place in the body politic for the professed man of science, unless he practised his science covertly as a physician or a priest. Even then its pursuit was attended with a considerable measure of personal peril. John Dee, it is true, dabbled in medicine, as he dabbled in most things that had any connection with the science of his period, and he was thereby of occasional service to his suffering fellows. For a time, too, his only means of subsistence came from a couple of wretchedly endowed country livings to which he was presented. But he was never recognised as a practising physician, or as a professed priest. His life's work was the pursuit of truth merely for the sake of elucidating it, an occupation unintelligible to his age. Apparently every aspect or form of truth was of equal importance to him; but, naturally enough, the direction in which he searched was influenced by his environment and the circumstances of his time. It was inevitable that such a man should sooner or later come into conflict with his age—a hard, unrelenting, pitiless age; and it was equally inevitable that he should be worsted in the fight. The spectacle of a strong man struggling with adversity is, we are told, a sight loved by the gods. We cannot help thinking that it is the spectacle of a sorely tried albeit misguided man, bent and well-nigh broken by the storms of fate, that has touched and quickened the womanly sympathy of the author of this book. Its compilation has evidently been a labour of love, or of the pity which is akin to it. Every page bears testimony to the patient care and trained skill with which the author has searched all available records and followed every clue which might serve to unravel the mystery of her hero's life.

John Dee was born in London in 1527. His father, Rowland Dee, was a gentleman server in the court of Henry VIII. The boy was sent to the Chantry School at Chelmsford, and thereafter, at the age of fifteen, to St. John's College, Cambridge, where he graduated in 1546, and was made a fellow of Trinity at its foundation by Henry VIII. Two years later, after taking his M.A. degree, he entered the University of Louvain, and thence passed on to Paris, where he gave lectures at the university on Euclid. Returning to England, he produced one or two astronomical works, and a book on the cause of the tides, presumably for the use of Edward VI. On the accession of Mary he got into trouble, and was thrown into prison on a charge of magic, and eventually of treason, and stood his trial by the Star Chamber. Nothing could be proved against him, and he was liberated, only to be handed over to the tender mercies of Bishop Bonner. He escaped even this ordeal, and subsequently presented Mary with a project for the establishment of a great national library in which to preserve "the treasure of all antiquity," the priceless collections of ancient literature which had been scattered by the dissolution of the monasteries and religious houses. Nothing came of the suggestion at the time. A couple of centuries had to elapse before the British Museum was founded, and it was only in the opening years of Queen Victoria's reign that keepers of the public records were appointed and the Historical Manuscripts Commission was brought into existence.

Easier times came to Dee with the advent of Elizabeth. He was already well known to her. She had corresponded with him when confined to Woodstock. His position as a mathematician had been established, and the name of the editor of Billingsley's "Euclid" was known throughout the learned world. The friend of Mercator—"my Gerard," as he calls him—he was esteemed, too, as a geographer skilled in cartography, and was constantly consulted by the great sea-captains of his time—Gilbert, Davis, Frobisher, Hawkins, Cavendish, and others of the remarkable band that created the sea-power of England. Dee had settled at Mortlake, where he was frequently visited by the Queen. Elizabeth had ever an eye for a comely man, and Dee was remarkably handsome, tall, stately, and of a dignified mien. The picture which Miss Fell Smith draws of his home life there, with his second wife—"his paynful Jane," as he calls her, the staunchest, truest friend he ever had—with the great Queen, either when "taking the ayre" or when on her way from Hampton Court or Isleworth to her palace at Greenwich, cantering up to his garden gate in order to get sight and speech of her courtly philosopher, is a charming piece of word-painting. But these were not altogether halcyon days for Dee. Elizabeth was gracious, even profuse in promise, but she was a very niggard in performance, and her astrologer was occasionally hard put to for the means of living.

Edward Kelley—*alias* Talbot—clipper, coiner, forger, and thief, now appears upon the scene, and the aspect of things becomes very grim. This man was Dee's evil genius. Their connection is one of the most astonishing and perplexing circumstances of his history. How Kelley could have acquired such complete ascendancy over his patron is almost inexplicable. Kelley was a first-class ne'er-do-well, a lover of loose company and of strong waters, and a consummate liar. He professed to be a clairvoyant, a skryer, or crystal-gazer, and Dee's passion for occultism was such that no tale of mystery or message from the spirit world was too gross or outrageous for him to swallow, as his own records of their *séances* demonstrate. Dee was an operative alchemist of no mean reputation, and the supposition is that Kelley sought to worm himself into Dee's confidence in order to gain information concerning the manufacture of the philosopher's stone, about which Dee never professed any knowledge. It is impossible here to go into any detail of the extraordinary partnership into which the pair entered, or to tell how they were induced, mainly at the instigation of a Polish adventurer, to wander, with their wives and Dee's children, on to the Continent, through Holland, North Germany, Poland, and eventually to Prague, where Kelley took service under Rudolph II., the "Hermes of Germany."

The story of that morose, half-witted, loose-living fanatic, who secluded himself for years in his gloomy palace at Prague, occupying himself with astrology, thaumaturgy, alchemy, necromancy, and every other form of aberration of which the human mind was then capable, is one of the most striking chapters in the book. Here Kelley was in a congenial atmosphere; he became wealthy—how is not very clear—flourished, in fact, like the bay tree, and was ennobled, only to fall more rapidly than he rose. He had previously shaken off Dee; he had no further use for him. The poverty-stricken, disillusioned man, after six years' wandering over Europe, now set his face once more towards Mortlake, only to find that, in his absence, his precious library of 4000 volumes had been rifled, and his instruments and apparatus broken by his neighbours. Well might he exclaim:—

"Have I so long, so dearly, so farre, so carefully, so painfully, so dangerously, fought and travailed for the learning of wisedome and atteyning of vertue, and in the end am I become worse than when I began? Call you this to be learned? Call you this to be a philosopher and a lover of wisdome?"

Could anything be more dramatic? The peaceful home on the banks of the Thames, into whose "silver" stream Dee's children occasionally tumbled without risk of being poisoned by the filth of Brentford; the surprise visits of the Queen; the advent of Kelley, and with him all the ghastly, skrying, crystal-gazing business—just as it is done to-day in Bond Street—communings with Annael, Anachor, Anilos, Uriel the Spirit of Light, Bobogel, Michael with his fiery sword, Gabriel, Raphael, Il, Ave, and the rest. Then comes Madimi, the first of the female angels who appeared to the pair, sometimes as "a pretty girl of seven or nine years attired in a gown of Sey, changeable green and red, with a train," and at other times as "a wench in white," and who had learned Greek, Arabic, and Syrian on purpose to be useful. Next enters the Mephisto of the story—Laski, the Polish adventurer, introduced by an angel named Jubanladec—who enjoined him to "live better and see himself inwardly." At his solicitation the pair decide to go with him to Poland. Then comes the journey across Holland, and along the devious peat-coloured waterways of East Friesland and out to sea by the islands up to Embden, and so to Oldenburg, Bremen, and Lubeck. Thence to Cracow, and eventually to Prague, where we have the mad Emperor, and all the diabolical doings in chicanery and fraud which bring the cropped-eared Kelley to his end. Lastly, we have the return of Dee—a ruined man, cheated by those he trusted, shunned by his acquaintance, scorned by his enemies—to the wrecked house at Mortlake he called home.

What a phantasmal tragedy it all seems! And yet it is sober history, capable of being verified in detail, as Miss Fell Smith demonstrates in her vivid, scholarly, and deeply interesting narrative.

T. E. THORPE.

THE PRECIOUS METALS.

The Precious Metals, comprising Gold, Silver, and Platinum. By Dr. T. Kirke Rose. Pp. xvi+295. (London: A. Constable and Co., Ltd., 1909.) Price 6*s*. net.

DR. ROSE, as is well known, is the author of the chief text-book on the metallurgy of gold; a book on the "Precious Metals" from his pen is, therefore, most welcome, and although in dealing with this subject details of processes and methods are for the most part left out, yet nothing of importance as introductory to the study of these metals is omitted.

The author states in the preface that his aim "has been to provide an introduction to the study of the precious metals and an elementary book of reference for those who do not wish to pursue the subject further." This aim has been admirably attained.

In the first chapters we have a brief but accurate summary of the history of gold from the earliest times, followed by an account of the properties of the metal and its compounds of special value to the metallurgist. The important subject, the alloys of gold, is treated at greater length in the fourth chapter, which is one of the most valuable parts of the book, and contains an account of these alloys, brief, it is true, but no essential points have been overlooked. The attention of the metallurgical student is especially called to this chapter, as it forms a comprehensive introduction, such as is not found elsewhere, to the detailed study of these interesting mixtures of gold with other metals. The constitution of these alloys, according to modern views, as deduced from freezing-point curves and microstructure, is ably and clearly explained. In the subsequent chapters dealing with gold, the occurrence of the metal in nature and the methods of extracting it from ores are dealt with. Commencing with the simplest and most primitive method of extraction, that of simple "washing" practised from the earliest times and culminating in the modern system of "dredging," the various processes of amalgamation are passed in review, and, finally, the so-called "wet" processes are considered. Of the latter, the cyanide process, to which we owe the extraordinary production of gold in the Transvaal, is dealt with at considerable length in the eighth chapter.

Silver, now of much less importance than gold, since it is no longer in use for the standard coinage of most countries, occupies only about half the space given to the nobler metal.

The alloys, compounds, and ores of silver are first discussed, and then methods of extraction. The important methods are described, and even those which have become, or are becoming, obsolete receive fitting attention. The time-honoured *patio* process in Mexico, where the climate and other conditions were specially favourable for its success, which has produced many millions sterling of the metal, has evidently had its day, is being replaced by the modern cyanide process, and is now mainly of historical interest. The same is true of other "wet" processes in many silver-producing districts.

An entire chapter is devoted to the processes employed in the refining of gold and silver, operations dealing annually with enormous values. Thus gold to the value of 50,000,000*l.* is refined every year by the sulphuric-acid process, 12,000,000*l.* by the chlorine process, and about 4,000,000*l.* by electrolysis.

The chapters on assaying, minting, and the manufacture of gold and silver wares are written with great clearness, and give the best brief and trustworthy account which has yet been published on these subjects. They will be read with interest by both technical and non-technical readers. Platinum, although not usually included in the term "precious metals," yet, being in common use and more valuable weight for weight than gold, has been rightly given a place in the book. The condensed account given of it deals with its occurrence, properties, alloys, extraction, purification, and assay.

The volume concludes with a series of statistics relating to the production and consumption of the precious metals.

The accounts of the various operations by which these metals are extracted from their ores and refined or adapted for minting or industrial use, although brief, are clear and accurate, and the essential points in each process on which its success depends are carefully set forth. A valuable feature, too, is the chemical reactions and changes which occur in the operations, and the principles on which they are based, which appear under each metal.

Dr. Rose is to be congratulated on his book. He has succeeded in compressing within the limits of 295 pages an excellent summary of the metallurgy of gold, silver, and platinum, marvellous in conciseness, quite up-to-date, and without the omission of anything of serious importance.

It deserves many readers, and can be strongly recommended to metallurgical students, by whom it can be studied with advantage before or at the same time as the larger text-books. W. G.

FLOWER CULTURE.

Beautiful Flowers and how to Grow Them. By Horace J. Wright and Walter P. Wright. Pp. 198. (Edinburgh: T. C. and E. C. Jack, n.d.) Published in seventeen parts at 1*s.* each, or two volumes at 10*s.* 6*d.* each.

THIS work will take a high place amongst recent publications dealing with the popular and fascinating art of floriculture. The authors have made a selection of the best and most beautiful flowers for cultivation in the garden and greenhouse. These flowers, numbering 100 in all, are illustrated in full-page coloured plates, which are excellent reproductions of flower paintings by such well-known artists as Beatrice Parsons, Eleanor Fortescue Brickdale, Anna Lea-Merritt, Hugh L. Norris, Lilian Stannard, Margaret Waterfield, A. Fairfax Muckley, and Francis E. James.

Such a collection affords a very valuable guide to amateurs as to which flowers are likely to give them most pleasure, and, in the majority of cases the kinds presented will be found amply sufficient for their study; but, not only so, the plates will prove useful in two further directions. In the first place, many of the pictures depict the particular flowers grouped with other kinds with which they harmonise perfectly in the garden, and, in the second place, as the paintings were in most cases prepared from first-class specimens, they set before the amateur a high standard of culture he will do well to emulate. Both these lessons are given in such plates as a "Bed of La France Roses," "Dwarf and Climbing Roses, with Zonal Geraniums," "Madonna Lily (*Lilium candidum*) and Roses," "Pyrethrums and Lupins," "Foxgloves and Poppies," "Asters, Phloxes and Sweet Peas," "Hippeastrums," "Single Dahlias," "Rosearch and Campanulas," "Hardy Chrysanthemums," and "Water Lilies." In certain others a supremely satisfactory result is obtained by showing a single plant depicted in all its glory, such, for instance, as

"Fibrous-rooted Begonia," in which the peculiar form and colour of a well-flowered plant are clearly set forth; *Lycaste Skinneri, Masdevallia Harryana,* and *Paphiopedilum* (*Cypripedium*) *Curtisii.*

It will be seen that orchids are well represented; indeed, the subjects are selected from almost every class of flowering plant; even the window garden is not forgotten, but, on the contrary, one of the plates illustrates a window-box filled with suitable plants in full flower. It can be said of only a small number that they fail to rank with the best, and in these few cases the original drawings were insufficiently definite in character or the plants depicted were scarcely satisfactory specimens.

So far we have referred only to that portion of the work which answers to the first half of the title, namely, "Beautiful Flowers," but in the text the second half of the title is justified, "How to Grow Them." The authors, being well familiar with their subjects, have related in pleasant, but plain, language all the details of cultivation that are necessary to enable the merest amateur to obtain success. It is satisfactory to note that this is done without the petty gossip and extraneous information that mar so many modern gardening books. In short, the writing, though pleasantly entertaining, is serious, and its main object, namely, that of imparting information, is always kept in mind. Part i. is exclusively devoted to the rose, which is treated at greater length than most of the subjects. Carefully compiled lists of roses specially suitable for particular forms of culture will save the amateur a great amount of research in catalogues, which is seldom satisfactory unless the cultivator has already considerable knowledge of the habits of the different types. Roses are followed by chapters on bulbs, which extend into part iii. Then follows a long article on hardy herbaceous plants, these being amongst the popular flowers of the day.

In part vi. herbaceous plants give place to rockery plants, and these to greenhouse and stove plants. In succeeding parts articles are devoted to sweet peas, carnations, dahlias, chrysanthemums, and all the most beautiful garden flowers, until near the end we come to the floral aristocrats, the orchids. There is a good index, and, in addition to the coloured plates, there are line drawings inserted in the text for the purpose of illustrating some of the cultural processes, such as budding, grafting, and other systems of propagation, also potting, tying, &c. The publishers may be congratulated on the excellent type and the general good appearance of this book, which is suitable for the drawing-room table.

BRITISH CATTLE.

The Evolution of British Cattle and the Fashioning of Breeds. By Prof. James Wilson. Pp. viii + 147. (London: Vinton and Co., Ltd., 1909.) Price 7*s.* 6*d.* net.

THE author of this book exhibits a considerable knowledge of the literature which bears upon the subject of the origin and development of British cattle. His references range from Cæsar's Gallic war to Thomson's recent book on heredity; they embrace not only husbandry in the old and agriculture in the new sense, but political and social history, and such details of the modern sciences of palæontology and Mendelism as are necessary for his purpose. Thus a knowledge of the habits of the peoples dealt with and of the circumstances affecting them at various times is brought to bear upon the problem of the migration of cattle and of the blending of different breeds in olden days, while the evidence he has culled from various writings of the seventeenth and eighteenth centuries is especially noteworthy and valuable to the student of heredity, inasmuch as it throws light on the causes which influenced the establishment of modern breeds during a period of which but little is generally known of stock breeding.

In his opening words the author asserts that it will be his duty to question and sometimes to destroy many fondly cherished beliefs as to the origin, history and evolution of the cattle of these islands. We think he has fulfilled that duty in a clear and convincing manner, and not only so, but has succeeded, as he hoped, in placing before his readers a sounder knowledge of the subject.

After a chapter on *Bos primigenius,* in which he disposes of the evidence advanced to show that this species has ever been represented here, he quotes the work of many modern palæontologists to demonstrate that *Bos longifrons* is the species which was present in the Neolithic age, and was the original native breed. It was this black breed, he says, which was driven with their Celtic owners before the successive invaders of Britain, and remain till this day in Scotland, Ireland, Wales, Cornwall, and the north of England.

He then claims that with the Romans came the white cattle of Southern Europe, from which the wild white cattle found at the time of the Norman invasion and the present wild herds are derived. That with the Anglo-Saxons came the red cattle which dominated the south of England down to the eighteenth century, and of which our Lincolns, Devons, Herefords, Norfolks, Suffolks, and Sussex are the representatives; while with the Norse people came the polled cattle.

After the Norman conquest until the seventeenth century he believes there was but little migration of cattle about the country, and that not until later still was crossing of breeds at all freely carried on. What he calls the "Dutch invasion" of cattle in the seventeenth and eighteenth centuries, caused by England's sympathy with the Netherlands, gave rise to the first shorthorn blood, and, as at this time "landowners had become business men," great impetus was then given to breeding.

He then deals in an admirable manner with the production and evolution of the various breeds which exist to-day; he calls to his aid Mendel's theories, and shows their practical value for the elucidation of such complex problems.

Especially interesting are his chapters on the causes, natural and artificial, which stimulated or checked the spread of the Hereford, longhorn, shorthorn, and Aberdeen Angus breeds; on Bakewell, Charles Colling, Hugh Watson, and other great breeders, and how they all brought their special breeds to perfection, first by their judgment and ability to select good stock, secondly, by judicious inbreeding, and, thirdly, by ruthlessly discarding unsatisfactory animals.

We have no hesitation in recommending this book to all who are theoretically or practically interested in the subject of breeding.

GEOGRAPHICAL MANUALS AND GUIDES.

(1) *A General Geography of the World.* By H. E. Evans. Pp. xii+439. (London: Blackie and Son, Ltd., 1909.) Price 3*s.* 6*d.*

(2) *The Oxford Geographies.* (Oxford: Clarendon Press, 1909.) (*a*) *The Practical Geography.* By J. F. Unstead. Part i, pp. 120; part ii, pp. 112; complete in one volume. Price 2*s.* 6*d.* (*b*) *The Elementary Geography.* By F. D. Herbertson. Vol. i; *A First Physiography.* Pp. 80. Price 10*d.* Vol. iii; *Europe, excluding the British Isles.* Pp. 112. Price 1*s.*

(3) *Cambridge County Geographies. Norfolk.* By W. A. Dutt. Pp. viii+156. *Suffolk.* By W. A. Dutt. Pp. viii+136. *Hertfordshire.* By R. Lydekker. Pp. ix+173. *Wiltshire.* By A. G. Bradley. Pp. xi+156. (Cambridge: University Press, 1909.) Price 1*s.* 6*d.* each.

(4) *By Road and River: a Descriptive Geography of the British Isles.* By E. M. Wilmot-Buxton. Pp. viii+154. (London: Methuen and Co., 1909.) Price 2*s.*

(5) *A Systematic Geography of the British Isles.* By G. W. Webb. Pp. viii+94. (London: Methuen and Co., 1909.) Price 1*s.*

(6) *Highways and Byways in Middlesex.* By W. Jerrold. Pp. xviii+400. (London: Macmillan and Co., Ltd., 1909.) Price 6*s.*

(7) *Growls from Uganda.* By Critolaos. Pp. 120. (London: Elliott Stock, 1909.) Price 2*s.* 6*d.* net.

(1) IF the student of geography can be taught to appreciate the value of a work of general reference, strictly arranged on a systematic plan, Mr. Evans' "General Geography" should meet with a demand. But it is not difficult, on the other hand, to imagine the school-child quailing before these serried ranks of facts, figures, and names, baldly presented, thrust forward by means of heavy-faced type, summarised (where there is need) in tables. It is to be hoped that no attempt is made, in these days, to teach geography out of such a book alone; but as a medium for refreshing the memory on essential points before an examination, it should be of great value. To enhance this value, a number of examination questions are given. Another noteworthy feature is that the index is made to serve as a guide to pronunciation, a matter in which students (and, for the matter of that, most other people) are commonly at fault owing to the difficulty of obtaining guidance in it.

(2) Mr. Unstead's "Practical Geography," as its name suggests, is a guide to practical work in geography. The guidance is provided by series of exercises, each group of which is preceded by an introductory statement. There are two parts in this volume. The first deals with map-reading, field work (*i.e.* the study of local geographical features on the spot), weather, and the British Isles. The second part is for students somewhat more advanced; it deals with map-making, weather changes, and their causes, the form and movements of the earth, the principal countries, and the comparative growth of population and development of commerce in Great Britain and other countries. Full directions are given for plotting on maps or illustrating by diagrams the various classes of geographical information, under the above headings, which are capable of such treatment. The exercises appear to be carefully thought out and suggestive, and ought to interest every student who once acquires an aptitude for them.

It would be hard to keep the requirements of the most elementary teaching more carefully in view than Mrs. Herbertson has in the two volumes of "The Elementary Geography" under notice. There is certainly an art in writing from this point of view. The two volumes are slight, but must needs be so. Simplicity in language and construction of sentences has been strictly adhered to. In this series the extreme value of illustrations has been realised, and some good photographs, selected according to their relevance to points in the text, are provided, with an explanatoin beneath each. A few simple exercises are provided for each subject taken up. These little volumes should supply a real need; their use as an introduction to geography must be manifest, in contrast with volumes of stock questions and answers.

(3) The four volumes of the "Cambridge County Geographies" now under notice are by different hands from those previously commented upon in these columns. While they adhere strictly to the model laid down for the whole series, the style is somewhat less rigid than that of the earlier volumes, and this is undoubtedly an improvement. Line drawings have not been used in the present volumes, and the photographs call for particular commendation as being well chosen and well reproduced. It may be repeated that the series deserves every encouragement, and it is to be hoped that it will be carried to completion in the same good style as marks Mr. Dutt's works on the two eastern shires, Mr. Lydekker's on Hertfordshire, and Mr. Bradley's on Wiltshire. The volumes are really remarkable value for their price.

(4) A school-book with the title "By Road and River," suggests something of a novelty. And Mr. Wilmot-Buxton's treatment of geography as a school subject is a decided departure from the ordinary lines. For the most part, we like it very well, and so should the children who learn from it. Premising that most children have no great opportunity for learning geography by the very best method—travelling—the author invites them to "*pretend* to go on journeys from place to place" by rail, road, or river. The result is instructive and entertaining, even if the author occasionally goes rather far in colloquialism in order to keep his style attractive. Moreover, the sketch-maps and illustrations are quite above the average in such books—the illustrations are particularly well chosen. A few questions for exercise accompany each chapter.

(5) Mr. Webb's "Systematic Geography of the British Isles" forms a complete contrast to Mr. Wilmot-Buxton's book just noticed. The two might advantageously be used together, Mr. Wilmot-Buxton providing lighter reading to alleviate the hard facts which Mr. Webb makes little attempt to soften by picturesque writing. The study of geography in the skeletonic form in which Mr. Webb presents it is no doubt a necessity, and his book is a model of careful arrangement. He lays a greater stress than usual on geological formation, tabulating and explaining the different rocks found in these islands as simply as possible. A point open to criticism is found in the historical notes sometimes attached to the names of chief towns. Some of these remarks, in order to be understood, would either presuppose detailed historical knowledge, or necessitate so long an explanation that they had better have been omitted.

(6) The volume on Middlesex in that favourite series, "Highways and Byways," takes a high place among its companions. Mr. Hugh Thomson's illustrations are charming; we could almost blame them because they even beautify some of their subjects, when the artist shows us picturesque fragments divorced from the unlovely surroundings characteristic of suburban villages. The author admirably practises the style best suited to these volumes, a blend of pleasant description and historical gossip. It is well that such history should be preserved in accessible shape, when so much of the external evidence for it has been effaced.

(7) We cannot pretend to find much value in "Growls from Uganda." It is true that the author gives us some impressions, conveyed by a very ready pen, of his life in Uganda and his travels in British Columbia, and in these two countries he presents us with a perfect contrast, if nothing else. But the essays in which he offers views on various features of social life in England, even though they touch upon genuine abuses, seem generally to show little more than a mastery of the obvious, or to provide (as in the case of the tirade against motor cars) little else than a protest against the inevitable. Frankly, we should not have supposed these parts of the book worth printing, from whatever quarter of the globe they had been addressed.

O. J. R. H.

OUR BOOK SHELF.

Weather Indicator. Compiled and designed by Wm. Ballance. (London: G. Philip and Son, Ltd., n.d.) Price, in sheet form, 2*s.* 6*d.*; mounted, &c., 3*s.* 6*d.*

THIS is an issue in map form of what the publishers term a "weather indicator," to be obtained either in a sheet or mounted on rollers. The notes, tables, &c., have been compiled by Mr. W. Ballance, and the publishers suggest that the "weather indicator" will be found useful for schools, clubs, public libraries, hotels, boys' brigades, and boy scouts. The information given seems too elaborate, and might easily have been rendered more simple; it is not very scientific, but it probably aims to be chiefly of a popular character. Many of the so-called weather signs which are collated, especially those relating to the movements of animals, birds, and insects, have been handed down to us from the ancients, and are somewhat amusing. For country life, some quoted should undoubtedly receive attention, but the general belief in all would tend to much confusion. For town life many are altogether inapplicable. Such statements as "A white frost never lasts more than three days," "Quick thaw foretells long frost," "Hoar frost predicts rain," are bold, but probably incorrect. The wind scale given is not in accordance with recent knowledge; the equivalent velocity in miles per hour, and equivalent wind pressure in pounds per square foot for the several units of the wind scale, are very different from those now generally accepted. To be told as a sign for fair weather the barometer should be steady, or rising about 0·004 inch per hour; for rain falling slowly about 0·004 inch per hour; for wind falling gradually about 0·011 inch per hour; for wind and rain falling moderately about 0·015 inch per hour; and for stormy weather falling or rising rapidly about 0·021 inch per hour is precision which meteorologists have no knowledge of, especially when most of our barometers only read to hundredths of an inch.

Science and Singing. A Consideration of the Capabilities of the Vocal Cords and their Work in the Art of Tone Production. By Ernest G. White. Pp. 72. (London: The Vincent Music Co., Ltd., n.d.; Boston, Mass.: Thomas J. Donlan, 1909.) Price 4*s.* 6*d.* net.

THE writer of this book endeavours to show that the tones of the human voice are not produced by the vibrations of the vocal cords, but by means of movements or pressures of the air in the sinuses found in the frontal, supermaxillary, sphenoid and ethmoid bones, and which all communicate with the cavities of the nose; in short, his theory may be called sinus tone production. In our opinion the author has not succeeded in establishing his position. The facts of anatomy and physiology, and the data of experiment, are entirely against him. Nothing is more certain than that the vocal cords vibrate, and, on the other hand, one cannot conceive how vocal tones could possibly be produced by the cavities we term sinuses. These, no doubt, have their effect in modifying the qualities of vocal tones by resonance, and the quality of a so-called head voice may be so explained. The merit of the little book is that it is written in an interesting, breezy style by one who is obsessed by an idea, and that it is illustrated by a number of beautiful diagrams, evidently from actual photographs, showing the anatomical position of the various sinuses. The various pictures are admirable.

J. G. M.

Butterflies and Moths of the United Kingdom. By Dr. W. Egmont Kirby. Pp. lii+468. (London: Geo. Routledge and Sons, Ltd.; New York: E. P. Dutton and Co., n.d.) Price 7*s.* 6*d.* net.

THIS is a book comprising descriptions of the larger British lepidoptera (macro-lepidoptera), with coloured figures of them all in their perfect state, and many in the larval stage. There are also a few pages given to the micro-lepidoptera, with coloured illustrations of their characteristic species. It is a book of the popular rather than the scientific order, one for information and reference useful to collectors who wish to know where and when to find the objects of their pursuit. The coloured plates, of which there are no fewer than seventy, each comprising usually some twenty or thirty figures, are, as might be expected from the price of the work, not of a high order, but are often good, and probably always sufficient for the purpose of recognition, which is the main value of a work of this kind.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

A New Oceanographical Expedition.

IN NATURE of November 18 (p. 71) there is a notice of a new oceanographical expedition, to be undertaken by the Norwegians in their surveying vessel *Michael Sars*, on the suggestion of Sir John Murray, and mainly at his expense. It is very gratifying to meet with cooperation of this kind in the prosecution of deep-sea research, and the investigation of the portion of the North Atlantic contemplated in the programme cannot fail to furnish interesting and useful results.

In the account of the expedition I note the following passage:—"The application of methods of high precision to the determination of the temperature and salinity of sea-water has yielded results which have raised considerable doubt in the minds of some investigators as to the validity of the earlier observations made by the *Challenger* and other expeditions, and the cruise of the *Michael Sars* should not only afford much entirely new information, but provide a means of valuing the earlier work."

As chemist and physicist of the *Challenger* expedition, I feel that this is a reflection, not only on the name of Challenger, but also on myself. I was a professional chemist of recognised standing at the date when the expedition was planned, and it was to this fact that I owed my selection for the post nearly a year before the ship sailed. During the whole of this time I was occupied with the study of the work to be done and of the methods to be employed in doing it. Some of these were devised by myself, and none were approved before they had been thoroughly tested on land; nor were they finally accepted until they had passed the probation of the first three months at sea. The regular work of the expedition began with the sailing of the ship from Teneriffe on February 15, 1873. By this time the scheme of the routine work of my department had taken definite shape, and it suffered but little alteration during the cruise. All the actual work was done by myself, and no method was employed which I had not myself tested and found to give, in my hands, thoroughly trustworthy results.

I think it is due to me and to the readers of NATURE that the investigators, in whose minds doubts have been raised as to the validity of the *Challenger* observations, should state them, with the grounds on which they rest, and also indicate how they expect the cruise of the *Michael Sars* to provide a means of valuing the earlier work.

November 27. J. Y. BUCHANAN.

Gametogenesis of the Sawfly *Nematus ribesii*. A Correction.

IN the *Quarterly Journal of Microscopical Science*, vol. li., 1907, p. 101, I described observations on the gametogenesis of *Nematus ribesii*, some of which subsequent work has shown to be erroneous. Since my statements have been quoted in several recent papers, I think it necessary to correct the mistakes as far as possible, although I have not yet reached a satisfactory solution of the phenomena. The errors arose partly through misinterpretation of the phenomena observed and partly through imperfect fixation, for I find that, unless the material is very accurately fixed, the chromosomes tend to adhere together and give the appearance of a smaller number than the true one. The same cause has led other observers to make similar mistakes.

Re-investigation of Nematus shows, in the first place, that there is only one division of the spermatocytes; the first division described in my paper is not a true mitosis, but is probably comparable with the abortive division observed in the spermatogenesis of the bee. I have not yet been able to determine the chromosome number with certainty. In the spermatogonia the number appears to be about sixteen, and that in spermatocyte mitoses about eight, but if eight is the true reduced number, the occurrence of sixteen in the spermatogonial mitoses of larvæ derived from parthenogenetic eggs is unexplained. In the bee, and as I find also in a Cynipid (to be published shortly), the spermatogonial number is the same as that of the spermatocytes.

I have not yet obtained fresh material for re-investigation of the maturation of the egg, but the results of my recent work on the spermatogenesis make it clear that my observations on the chromosomes in the polar divisions also require revision.

But the behaviour of the chromosomes in *Nematus ribesii* is so difficult to follow that it is possible that the true interpretation will be obtained only by the discovery of some nearly related species in which they are more clearly distinguishable. LEONARD DONCASTER.

University of Birmingham, November 27.

Are the Senses ever Vicarious?

[PROF. MCKENDRICK has sent us the subjoined letter received by him, and his comments upon it.—ED. NATURE.]

MY attention has just been directed to a letter which appeared in NATURE of March 11 (vol. lxxx., p. 38). It was signed by Prof. McKendrick, and dealt with the vexed question of the blind and their faculties.

I am a blind man, and have mixed with blind people of all ages for the past thirty years. You will grant that I ought to know something about the question you discuss in your letter.

Permit me to thank you for what you say about the popular notion that when a person loses his sight he is compensated by a gift of ability in one, if not all, his other faculties. The intelligent blind know how foolish this idea is, and constantly protest against it. The public, however, insist upon its accuracy, and calmly assume that the blind do not grasp the point at issue, or affirm that those who protest are unbelievers in the goodness of God. This assertion of compensation leads to all sorts of ridiculous notions, and has a very pernicious practical effect. The very people who assert the theory of compensation are among the number who shrink from providing facilities for the proper training and employment of the very gifted people they profess to look upon as the possessors of special talents. They impute to us the possession of all kinds of striking abilities, yet they decline to allow the specially talented to do what would earn or help to earn a livelihood. We are credited with mavellous powers in music, basket-making, &c., and yet when we assert our claim to live the ordinary life of the citizen these people are shocked at our audacity.

Now, the overthrow of the theory that we are specially compensated for the loss of sight will destroy the false impressions regarding our wonderful memories and all the other fantastic notions, and the way will be opened for common-sense treatment of the training and employment of the blind. It is notorious among the blind themselves that numbers of them are not at all musical, and that mechanical ability is not a conspicuous feature. Many blind are very deficient in hearing, in smell, and in the sense of touch itself. My own experience has compelled me to take heed of the varying degrees of what I shall call, for want of a better name, ear-power. The same variety exists in touch-power and memory-power. I should like to refer to these as well as many other interesting phenomena, but I fear I must content myself with asking your kindly attention to a problem which has baffled me for more than twenty years. Why does the voice call up before me the upper part of the speaker's face, and enable me to form a picture of the expression of the speaker? The expression of the eyes is frequently as vividly before me as when I could see. When people are speaking to me, they are never on guard to control their countenance as they would be if conversing with a sighted person. I am thus enabled to get a picture of the play of their emotions which helps me to come to conclusions as to character, &c. The lower part of the face was only once made visible to me, so that I could feel sure about it. I know when a person smiles, frowns, when the face lights up with an intelligence or when apathy and want of perception cloud the countenance. Sometimes I can follow the line of the glance and can point out where it would strike. When listening to public speakers I like to sit at an angle to them, and not in front. Can you point to anything that will aid me to come to a sensible conclusion on this matter of the voice conveying the picture of the upper part of the face, and thus help me to fathom a question which I am persuaded contains the key to many other problems as to the constitution of sound and the organ of sound?

George Irons Walker.

Westbury Street, Sunderland, October 28.

With reference to Mr. Walker's interesting letter, which bears out the opinion of Prof. Kunz and others that there is no special development of the other senses in those who have lost the sense of sight, I feel at a loss to give an adequate explanation of the curious experiences described by Mr. Walker. The only suggestion I would venture to make is that Mr. Walker may, by long and almost unconscious practice, have learned to associate certain tones of the voice, as regards quality of tone, with certain movements of the head that he supposes are made by the speaker at the time he utters the words. Tones of inquiry, surprise, reproach, affection, interest, have each a certain quality indicative of states of feeling (unless they are produced by mimicry), and the blind man may draw conclusions as to movement and state of feeling on the part of the speakers. He has then what Mr. Walker calls "a picture of the play of their emotions." I cannot explain why Mr. Walker has almost invariably a picture of the upper part of the face, nor why he prefers to sit at an angle to a public speaker instead of in front. His experience supports the view that the blind have not more acute sensory perceptions than those who see, but that they have cultivated the habit of close attention. This, in turn, stimulates their imagination, and gives them mental pictures of external things that are of no special importance to those who see.

John G. McKendrick.

Movements of the Red Spot Hollow on Jupiter.

Transit estimates of the Red Spot Hollow on Jupiter, obtained between 1908 December 20 and 1909 June 12 inclusive, show that that object exhibited an average monthly increase in longitude of 1·03°. Its motion, however, was not constant, inasmuch as it remained practically stationary in longitude during the last three months (April to June) of the apparition. The rotation periods of the three selected points of the Hollow, namely, the two shoulders and the middle, work out as under:—

Date	Long.	No. of transits	Elapsed rotations	Mean daily drift	Rotation period
			p. Shoulder.		
	°			°	h. m. s.
1908, Dec. 20 ... 1909, June 7 ...	358·5 4·8	16	408	−0·0376	9 55 42·2
			Middle.		
1908, Dec. 20 ... 1909, June 12 ...	13·6 18·4	15	420	−0·0274	9 55 41·8
			f. Shoulder.		
1908, Dec. 20 ... 1909, June 12 ...	31·1 37·1	20	420	−0·0344	9 55 42·1

The mean rotation period of the Hollow, therefore, appears to have been, as nearly as possible, 9h. 55m. 42·0s., a period which is 1·4 seconds longer than that of the adopted value of System II.

At the commencement of the observations, in December, the middle of the Hollow crossed the central meridian about twenty-three minutes subsequent to the passage of the zero meridian, and half an hour at the close of the apparition in June. This lagging behind may be regarded as a distinctly normal movement on the part of the Red Spot.

When the planet was observed last month as it emerged from the sun's rays, the Hollow was found to have moved at an accelerated rate of velocity during the unobserved interval since June. From transits obtained on October 15, 25, and 30, the deduced mean longitude of the middle of the Hollow was then 16·4°. This shows a decrease of 2° when compared with the longitude for June. It is evident, therefore, that the motion of the object had latterly become quickened. Had the Hollow continued to drift at the same rate as was exhibited from December to June, it would have crossed the central meridian ten minutes later than was actually the case last month. Owing to this slight displacement in longitude, the rotation period from June to October was shorter than that for the previous six months, and works out at 9h. 55m. 40·0s.

Secondary Kathode Rays.

In a letter to Nature of April 2, 1908 (vol. lxxvii., p. 509), I described some experiments of mine which showed that for the corpuscular rays produced in metals by Röntgen rays there was a lack of symmetry between those coming from the side of the metals on which the primary rays were incident and those coming from the side from which the primary rays emerged. The ionisation produced by the emergence secondary corpuscles was, in general, greater than that produced by the incidence corpuscles. This was in accordance with Prof. Bragg's results for the corpuscular rays produced by γ rays (Nature, January 23, 1908, p. 270).

Since writing the above I have endeavoured to see if this lack of symmetry was dependent on the penetrating power of the primary Röntgen rays. Experiments were carried on only with gold and silver, and gave the following results. The average of four determinations with soft primary rays on silver showed the ionisation produced by the emergence to be 1·11 times as great as that produced by the incidence corpuscular secondary rays; eight determinations with hard primary rays gave an average ratio of 1·21. Five determinations with soft primary rays on gold gave the ratio of emergence to incidence ionisation as 1·03; nine determinations with hard primary rays gave a ratio of 1·09. The probable error of the mean in each case was ±0·01. It would seem, therefore, that there is a slight variation of the asymmetry with the hardness of the Röntgen rays, certainly in the case of silver, and very probably in the case of gold, the harder primary rays causing the ratio of the emergence to the incidence corpuscular rays to increase.

Though the hardness of the Röntgen rays could be varied, they were probably always very heterogeneous. I hope soon to repeat my experiments, using more homogeneous Röntgen rays, which have been recently made possible by the experiments of Prof. Barkla.

Haven, Conn., November 17.

AN INTERNATIONAL MAP OF THE WORLD.

An International Committee assembled in London on November 15 to consider the form in which it is desirable to prepare a uniform map of the world on the scale of 1/1,000,000, or about sixteen miles to the inch.

The proceedings of this committee have aroused keen interest among geographers, and the results of its labours will be anxiously awaited. The meeting of this committee marks an epoch in map-making, and if its proposals are generally adopted, as no doubt they will be, there will be prepared a map of the whole world, uniform in design and execution, on a reasonably large scale.

Hitherto each country has, in the preparation of its maps, had in view solely its own requirements, and has made no effort to assimilate its maps to those of other countries, either in regard to scale, projection, method of representing hills, or in other points. Maps have been issued differing widely in these respects from those even of the adjoining countries.

The difficulty caused by this diversity of map design has long been felt, not only by those little versed in map reading, but by those who have constant occasion to work with maps.

It was not until 1891 that the first important step was taken towards obtaining a more uniform map of the world. In that year the International Geographical Congress at Bern raised the question, and the London Congress of 1895 passed a resolution recommending the scale of 1/1,000,000, or about sixteen miles to the inch, as suitable for a map of the world. This resolution was communicated to the various Governments in the hope that this scale might be generally adopted.

It was some time before this resolution produced much effect, but eventually Great Britain published a map of the United Kingdom on this scale, and commenced the publication of maps of Africa and Asia, while France and Germany commenced the issue and the United States the preparation of maps on this scale. Meanwhile the opinion of experts was coming round to the view that for the map of the world uniformity in many points other than scale is desirable.

At the meeting of the International Geographical Congress at Geneva in 1908 the subject was again considered, and it was decided to recommend for the 1/1,000,000 scale map the adoption of a uniform design, *i.e.* that the projection, methods of representing hills and other details, the conventional signs, amount of detail to be shown, and other points should be similar throughout. The various Governments were asked to prepare specimens on the 1/1,000,000 scale to illustrate their views as to style, &c.

Great Britain then invited the different Governments to appoint delegates to meet in London in order to consider draft proposals, which had meantime been elaborated, for the preparation of this map, and it was the delegates appointed in response to this invitation who recently met in London. The principal Powers of Europe, the United States of America, Canada, and Australia sent delegates, and the *personnel* of the committee was so strong that its recommendations must carry great weight.

Its report has not yet been published, but it may probably be assumed that the recommendations are substantially as given in the *Times* of November 22. These may be briefly stated as follows:—

(1) The adoption of the modified polyconic projection, and the division of the map of the world into sheets, each distinguished by a letter of the alphabet and by a name.

(2) A scale of kilometres, and, if desired, also of feet, to be printed on each sheet.

(3) Altitudes to be given in metres, and, if desired, also in feet.

(4) Ground forms to be shown by contours in brown and by coloured layers, as used in Bartholomew's maps and in some of the more recent maps of the Ordnance Survey. The contours to be at 100-metre intervals in the lower ground, and at greater intervals in the higher ground; ground forms not to be shown at altitudes above 7000 metres.

(5) Water to be shown in blue, perennial being distinguished from non-perennial water, also navigable from unnavigable rivers. Obstructions such as dams, locks, &c., to be shown, also fresh and salt marshes. Depths below the sea to be indicated by blue contours.

(6) Main roads to be distinguished from secondary roads, railways in running order from those under construction or projected; lines of telegraph, post offices, boundaries, towns and villages, &c., to be shown. A table of conventional signs was drawn up.

(7) Names to be in Latin character in the form adopted by the country in which the object is situated. Special rules were drawn up for translating names from other languages into the Latin character.

I think that all geographers will agree that these proposals, taken as a whole, are thoroughly sound and worthy of the distinguished geographical experts who form the committee; but there are some details of importance as to which assent to the proposals of the committee is likely to be less general, although probably the views of the committee will be widely accepted.

The scale of the map, about 1/16 inch to a mile, is sufficiently small to make it difficult to show a great deal of detail without overcrowding, and thereby detracting from the clearness of the map. In many countries it will be advantageous and also easy to show without overcrowding, all the detail contemplated by the committee, but in closely populated country such as parts of France, Germany, Great Britain, and the United States, it will, at any rate, be very difficult. If one studies the existing 1/1,000,000 scale map of England, which has perhaps rather less detail than the scale will admit of, it will be seen that the addition of much detail might overcrowd the map. It is not suggested that the committee proposes to show too much detail, but there seems to be a danger, unless great judgment is used, of overcrowding the map in close country, and it is to be hoped that in the preparation of the map of such districts this danger will be recognised and care taken to avoid it.

Another point on which opinions will differ is the recommendation that ground forms be shown by the layer system. This system is better suited for country with moderate altitudes, such as England, where it answers well, than for a map of the world, in parts of which the altitudes are great, and many would prefer ground forms to be shown by contours and shading. There is much to be said on both sides of the question, but there are undoubtedly some advantages in the method proposed by the committee, and no doubt in the end its judgment will prevail.

I will only refer to one other point, the only one on which I feel a difficulty in agreeing with the view of the committee. It is proposed to give all altitudes in metres. Now the area of the countries using the foot as a unit is very large, and the population is large in proportion to the area. To this large population the rendering of all heights in metres would be a great inconvenience. I do not think that on this scale it would answer to show, as has been suggested, both feet and metres. The question arises whether on this point absolute uniformity is essential. It appears to me that it is not, and that an endeavour might be made to give the heights in metres in countries in which the metre is the unit, and in feet where the foot is the unit. Of course, some give and take would be necessary in parts like the centre of Africa, so as to avoid numerous changes of unit, and hence some countries would have their heights given in the unit they are not accustomed to; but this would be a smaller matter than giving altitudes in a unit unfamiliar to all countries using the foot. The loss of uniformity which this would entail would, in my opinion, be a less evil than that of giving all altitudes over a considerable part of the world, including some of the busiest countries, in terms of a unit not ordinarily used in the business of the country.

I have called attention to a few points in which the proposals of the committee may be questioned, as it seems advantageous that such points should be discussed, but these points sink into insignificance compared with the solid and undisputed value of the work done by the committee. The convenience of being able to get a map of any part of the world, on a reasonably large scale, uniform in style and execution with any other part, will be great to statesmen, business men, travellers, and to all who use maps. To statesmen they should be of special value. International disputes and many mistakes have been caused by working on defective maps of varying scales; when this new map is issued, as no doubt it soon will be, one source of such errors will disappear. It may be wondered now that a uniform map of the world has not been sooner projected. None the less credit is due to those who originated the idea, who persevered in advocating it in spite of some discouragement, and have elaborated the details with such thoroughness as to make the success of the map practically sure.

DUNCAN A. JOHNSTON.

TUBERCULOSIS AMONG THE INDIANS OF NORTH AMERICA.[1]

THE increasing prevalence of tuberculosis among the North American Indians has for some time attracted attention, and the results of a detailed investigation of hygiene in the Indian reservations form the subject of a report by Dr. Aleš Hrdlička, published in the 42nd Bulletin of the Bureau of American Ethnology.

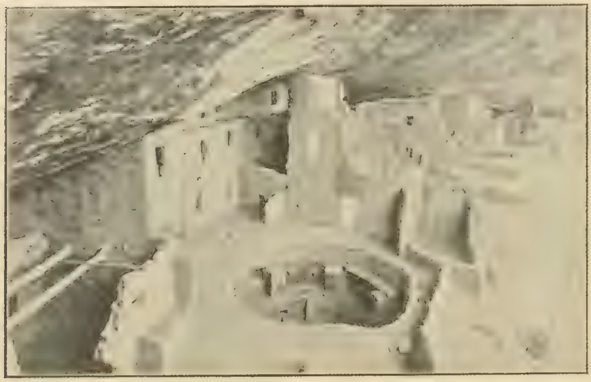

Fig. 1.—A Kiva of Spruce-Tree House—a large ruin in Mesa Verde Park, Colorado.

The facts disclosed in the course of this inquiry are striking and alarming. This disease, which threatens to exterminate the Indian population, seems not to have existed among the natives of the continent prior to the arrival of the whites. While the country was still largely unsettled they were accustomed to a natural and active life, were inured to hardship, and were, as a rule, provided with more suitable food. These conditions have changed with the advance of civilisation. At present the Indian is more susceptible to the disease than the white man; in other words, his system is less immune owing to the more recent introduction of infection among the race.

These inquiries sufficiently explain the etiology of tuberculosis among the inhabitants of the reservations. Infection is facilitated, particularly in the cold and rainy seasons, by the neglect of hygienic precautions, especially from overcrowding and lack of ventilation. No care is taken to destroy the infective sputum, the tubercle bacillus being dispersed by the common use of vessels, clothing, and musical instruments, while "pipe passing," the usual mark of hospitality, is common. In addition to these contributory causes, there seems to be now a well-established hereditary tendency, which is developed by exposure, dissipation, indolence, and other causes contributing to bodily weakness. There seems also to be little doubt that the disease is spread by milch cattle infected with tuberculosis. Lastly, the patient, with the well-known stolidity and resignation of his race, is unable to resist the progress of the disease as soon as he understands that he is infected.

The remedies suggested to improve this condition of things are increased attention to hygiene, disinfection of the sputum, and isolation of the sick. It is clear that there will be considerable difficulty in enforcing precautions of this kind among such a people. Dr. Hrdlička gives a significant warning that curators of museums should be on their guard against the danger of carelessly handling, without previous disinfection, articles, particularly fabrics, received from Indian homes.

The conditions of earlier Indian life are illustrated in an interesting way by the report published in the 41st Bulletin of the Bureau, by Dr. J. W. Fewkes, on the cliff-dwellings known as the Spruce-Tree ruins in the Mesa Verde National Park, Colorado. Here we find Kivas, or circular pit-dwellings, in connection with the series of caves once inhabited by a now forgotten race. With a view to mutual protection, a population of some four hundred souls was crowded within this narrow area. Dr. Fewkes believes that he can explain the reason why the Kivas are built underground and are circular in form, on the theory that both conditions are survivals from the ancient pit-houses or subterranean dwellings of a still earlier race. From this point of view the Kivas form the most ancient part of the existing ruins. These people lived in the age of stone, no metal implements, even those of copper, having been discovered. They had some belief in a world beyond the grave, because they laid mortuary offerings with the dead. Their conditions of life resembled those of the Pueblo population, and as these survived until comparatively modern times it is very difficult to assign a date to

Fig. 2.—Oglala Dwellings. Triple log-house under construction and temporary tent-house.

the present ruins. They lived by a rude kind of farming, growing maize, beans, and melons; their women had some skill in pottery. They seem to have used their underground Kivas as places where they carried on a constant round of tribal ceremonial. They lived a retired life, and were little influenced by foreign culture. The ruins have now been carefully restored under the supervision of Dr. Fewkes, whose report, fully illustrated, gives an excellent account of a strange forgotten race.

LOW-TEMPERATURE RESEARCH AT THE ROYAL INSTITUTION.[1]

A SUMMARY of the work carried on with the aid of the Hodgkins Trust is, by the authority of the managers, incorporated in the Proceedings of the Royal Institution every seven years. Like the preceding report, which chronicled the solidification of oxygen, the liquefaction of fluorine, and the liquefaction and solidification of hydrogen, the essay in which the achievements of the years 1900 to 1907 are described by Prof. Armstrong is again concerned mainly with low-temperature investigations.

No fewer than thirty-five original publications are referred to, the main feature running through them being the discovery and use of the charcoal vacuum, a practical advance only less important than the introduction of vacuum vessels in the manipulation of liquefied gases. At the temperature of liquid air the absorption is from six to thirty-four times as great as at 0°, and depends but little on the pressure, so that very high vacua can be produced. The density of the occluded gas is substantially that of the liquid, 0·06 against 0·07 for hydrogen, and 0·17 against 0·15 for helium. Owing to their slight absorption by charcoal at −185°, the presence of hydrogen and neon in air can be detected readily by connecting a vacuum tube with a vessel containing charcoal cooled in liquid air; if the gas be enriched by starting with a larger quantity and submitting it twice to condensation by cold charcoal, the spectrum of helium can also be detected.

The fact that helium is not condensed by charcoal at −185° was made use of by Prof. Onnes in the experiments which culminated in the liquefaction of helium, the one gas which had resisted all attempts to liquefy it at the commencement of the period under review; only by this means was it possible to maintain the purity of the helium and to ensure that the circulation of the gas could be maintained undisturbed by condensation of solid hydrogen and solid air. The indebtedness which he owed to Sir J. Dewar's discoveries was fully and generously acknowledged by Prof. Onnes in recording this great achievement.

ANNIVERSARY MEETING OF THE ROYAL SOCIETY.

THE anniversary meeting of the Royal Society was held as usual on St. Andrew's Day, Tuesday, November 30, when the report of the council was presented, and an address was given by the president, Sir Archibald Geikie, K.C.B. An account of the main subjects that occupied the attention of the council during the past year is given in the report, from which extracts are here subjoined. Other matters mentioned in the report have been referred to already in these columns.

REPORT OF THE COUNCIL.

Results of the National Antarctic Expedition.

The only part of the physical observations of the National Antarctic Expedition, of which the Royal Society undertook the preparation and publication, that remains to be completed is the second volume on meteorology, which is now in progress. It will consist chiefly of synchronous charts of sea-level pressure, with winds and temperatures, over the greater part of the southern hemisphere. It will thus embody, not only the results of the observations made by the *Discovery*, but information derived from many other sources. The preparation of these charts is in the hands of the Meteorological Office under Dr. Shaw. It is anticipated that this laborious task will be completed in time to allow the volume to be published next year.

Glass-workers' Cataract.

The inquiry into the disease known as glass-workers' cataract, instituted at the request of H.M. Government, and referred to in the last report, has been pursued during the year by the committee appointed by the council. The scheme of operations drawn up by the committee includes experimental research in the laboratory, and also investigations at some of the principal glass manufactories, with the view of obtaining data of the processes of glass-manufacture and of the incidence of the disease among operatives. Some progress has been made in this latter branch of the inquiry, but the work of the committee has been hindered by the refusal of certain glass manufacturers to allow the committee to visit their works. The experimental researches in the laboratory are proceeding.

The National Physical Laboratory.

The need for increasing accommodation is greatly felt in several departments. This is specially the case in the department of metallurgy, referred to by Lord Rayleigh in his address last year. With regard to this the executive committee of the laboratory report:—

"Investigations of very real importance have to be declined, because of the need of appliances, and the general scale of the arrangements is much too small. A site is available for a new metallurgical laboratory adjoining the chemical laboratory, and it is highly desirable that during the coming year active steps should be taken to secure the necessary funds. The committee commend this need to metallurgists interested in furthering investigations into the application of science to the practical treatment of metals and to other problems of importance."

The executive committee have nominated a special committee to raise the necessary funds for extension in this and other directions.

The most important event of the year, however, has been the work of construction of the national experimental tank, given to the laboratory with great generosity by Mr. A. F. Yarrow; this work is now well advanced. In April last Mr. Yarrow wrote to the secretary of the Institution of Naval Architects directing attention to the importance of such a tank, and offering to present a sum of 20,000*l.* on the understanding—

(1) That a tank of the most modern character can be established for a sum not exceeding 20,000*l.*, and that it be established at the National Physical Laboratory.

(2) That suitable provision be made, both as regards staff and means, for conducting research work, as well as for experimental investigations of a confidential character which private firms may desire, and for which they would pay suitable fees.

(3) That a sufficient sum be provided to ensure that the tank be efficiently carried on for a period of not less than ten years. This provision might take the form either of an endowment or of guaranteed subscriptions from shipbuilders and ship-owners.

Mr. Yarrow's letter continues:—"I believe that an adequate provision for maintenance would involve not less than 2000*l.* a year; that is to say, a total guarantee fund of 20,000*l.* would be required to maintain the efficient working of the tank for the above period."

In accordance with Mr. Yarrow's suggestions, a committee was formed by the Institution of Naval Architects to study the practicability of the scheme and the raising of the maintenance fund. Towards the end of the year this committee informed the executive committee of the laboratory that about half the funds required had been promised, and that it was anticipated that the remainder would be forthcoming in due course; they also asked for an expression of the views of the executive committee and a statement of the conditions under which the tank could be worked as a department of the laboratory. The executive committee replied that if the guarantee fund were now raised to at least 1200*l.* a year, and if the experimental tank committee would undertake to continue their endeavours to increase it further with the view of research, the executive committee would be willing to take the responsibility for the expenses of working the tank in accordance with Mr. Yarrow's proposal. The governing body of the laboratory have thus made themselves responsible for an expenditure which may amount to 800*l.* per annum for ten years, and will receive in return the fees which are expected to come from tests carried out for ship-builders. On his part, Mr. Yarrow has paid over cash and securities to the value of at least 20,000*l.* to the treasurer of the Royal Society, and the president and council have conveyed to him the cordial thanks of the society for his most generous action.

---

[1] Low-Temperature Research at the Royal Institution of Great Britain, London, 1900–7. Essay by Prof. H. E. Armstrong, F.R.S. II. The Charcoal Vacuum Septenate. Pp. 63. (Hodgkins Trust, 1909.)

During the year the executive committee have also, at the request of H.M. Government, undertaken important and onerous responsibilities on the scientific side of the experimental study and improvement of the conditions governing artificial flight.

International Catalogue of Scientific Literature.

The whole of the seventh annual issue of the catalogue has been published with the exception of D (chemistry), M (botany), O (anatomy), P (anthropology), and Q (physiology). These five volumes, as well as several volumes of the eighth issue, are in the press.

The International Council of the Catalogue, which had held meetings previously in 1900, 1904, and 1907, met again this year on June 3 and 4 in the rooms of the Royal Society.

The International Council made arrangements with the view of diminishing the cost of production of the catalogue, and also passed the following resolution:—

"That the regional bureaus be requested to confer, before April, 1910, with scientific workers in their several countries, so that any opinions and proposals of those to whom the catalogue is of consequence may be laid before the International Convention in 1910."

At the meeting of that convention important decisions must be made regarding the future of the catalogue; accordingly, the council of the Royal Society has appointed a committee to consider and report upon their relation to this undertaking.

Research on Tropical Diseases.

The investigations of the action of drugs upon trypanosomes, referred to in previous council reports, have been continued under the direction of a subcommittee, and accounts of the principal results of these investigations have been published from time to time. The latest progress report, by Mr. H. G. Plimmer and Captain Fry, "On the Experimental Treatment of Trypanosomiasis," appeared in Proceedings, B, No. 549, October 9.

During the present year the inquiry into sleeping sickness in Uganda has been actively pursued by the Royal Society's commission, which left England in October, 1908, under the direction of Colonel Sir David Bruce. Three papers on the work of the commission have been received from him during his stay in Uganda, and have been published in the Proceedings, viz.:—(1) "*Trypanosoma ingens*, n.sp."; (2) "The Development of *Trypanosoma gambiense* in *Glossina palpalis*"; (3) "A Note on the Occurrence of a Trypanosome in the African Elephant."

The second of these papers contains an account of an experiment carried out by the Commission, the results of which confirm the important conclusion arrived at by Dr. Kleine in German East Africa, that the tsetse-fly *Glossina palpalis* may be infective for a considerable period after the fly has fed on an infected animal. Previously it had been believed that the carrying of infection from a sleeping-sickness patient to a healthy person by the *Glossina palpalis* was a mechanical act, and that the power of transferring the disease was lost to the fly forty-eight hours after it had fed on an infected person. Dr. Kleine, however, has recorded observations of the fly remaining infective for much longer periods, extending up to sixty-six days, and now Sir David Bruce has reported further experiments, carrying the duration of infectivity as far as seventy-five days. This confirmation of Dr. Kleine's observations makes it necessary to revise previous conclusions on this point, the importance of which is obvious owing to its bearing on the nature of such preventive measures as have been hitherto attempted.

At the suggestion of Colonel Sir David Bruce, a conference, composed of medical (including veterinary) officers in British East Africa and Uganda, together with representatives of the administration of those protectorates, was held at Nairobi, in May, under the presidency of Sir David Bruce, to discuss and make recommendations as to preventive and remedial measures in regard to both human and animal trypanosomiasis.

Sir David Bruce is leaving Uganda this month, but arrangements have been made which will admit of the work of the commission being carried on after his departure.

Tyndall Donation.

During the current year Mrs. Tyndall, in pursuance of a wish expressed by her husband, the late Prof. Tyndall, has entrusted to the Royal Society the sum of 1000*l.*, to be administered at the discretion of the president and council for the purpose of encouraging and furthering research in all matters pertaining to mining, including such questions as ventilation, temperature, diseases incident to miners, and any other lines of scientific inquiry conducive to the improvement of mining and the lot of the miners.

PRESIDENTIAL ADDRESS.

In his presidential address, Sir Archibald Geikie referred first to the losses by death of distinguished fellows of the society since the last anniversary meeting. On the foreign list he had to record the decease of five men of wide reputation, namely, Albert Gaudry, Simon Newcomb, Anton Dohrn, Georg von Neumayer, and Julius Thomsen. The society also lost by death during the year the following fellows on the home list:—Daniel John Cunningham, David James Hamilton, Rev. W. H. Dallinger, Wilfrid Hudleston Hudleston, Harry Govier Seeley, Arthur Gamgee, Gerald Francis Yeo, Thomas William Bridge, Sir George King, Francis Elgar, Bindon Blood Stoney, George Gore, and William James Russell.

The special subject to which the president's address was devoted was the work in which the Royal Society is engaged. It is not commonly known that the weekly meetings and the publications to which they give rise, though they constitute the most important part of the labours of the society, so far as relates to the progress of discovery, form only a portion of a programme which is every year becoming fuller and demanding more time, thought, and funds for its accomplishment. Sir Archibald Geikie gave, therefore, a brief outline of the various directions in which the energies of the society are employed, in the hope that when some of the difficulties become more widely known, means may be found for adequately coping with them.

When the Royal Society was founded it was the only learned body in this country specially devoted to the prosecution of scientific inquiry, and such it continued to be for generations; but the rapid growth of science during the last century has shown that no single society can now serve to supply the needs of the whole vast field of investigation in every department of nature. Most of these departments, one after the other, have had special societies created for their exclusive cultivation, each of which records the progress of research in its own territory. At first the Royal Society, long accustomed to reign with undisputed sway over the whole realm of natural knowledge, was disposed to look with disfavour on this multiplication of separate and independent institutions; but that time has long since passed away. Subdivision is now admitted to be necessary, and, if properly directed, even desirable. Hence this society, like a proud parent, now rejoices in the growth and energy of the increasing family which has grown up around her, while she in turn is regarded with respect and esteem by the various members of that family, among whom there is a general desire to be enrolled in her ranks.

Nevertheless, it is impossible not to perceive that the rise of all these younger societies has materially affected the position of the Royal Society in regard to the general advance of modern science. This society is no longer the general depository of the records of that progress in all its branches. So completely, for instance, do the Geological and Chemical Societies provide for the requirements of their respective fields of investigation that communications from these fields come now comparatively seldom before us. If one desires to follow the modern growth of geology or chemistry, one must turn for its record to the publications, not of the Royal Society, but of the two learned bodies that are specially devoted to the cultivation of these sciences. Nor can we see any reason why this process of devolution should not continue in the future. Hence, if the system of reading and publishing papers which has been in use here for so many generations is to be perpetuated without modification, there may come a day when every great department of natural knowledge will be provided with its own special society, and then we may ask in anticipation, what will be left for the meetings of the Royal Society? For myself I do not believe that such a time of impoverishment ever will befall us. We cannot, and would not if we could, do anything to prevent the foundation of fresh societies for sciences that have not yet been provided with them; but we may so adjust our programme as to bring it into harmony with modern conditions, and thus to maintain and extend the prestige and usefulness of the Royal Society. The danger to which I have referred, however, is by no means imaginary, and it should be faced before it has time to become serious.

Some years ago the society departed from the time-honoured practice of dealing with natural knowledge as one great subject, and now groups its papers in two separate series, one devoted to physical (A) and the other to biological (B) questions. It is undoubtedly a considerable convenience to have the memoirs in each of those two great divisions gathered together into a separate series of volumes. More recently the practice has grown up of introducing a similar principle in the grouping of papers to be read at the weekly meetings of the society. It was hoped that by taking the physical papers on one day and the biological communications on another a better attendance could be secured, especially of the representatives of each division. I cannot say that this arrangement has been attended with the success which was anticipated.

That there are some practical advantages in this separation of subjects cannot be gainsaid, and I would not for a moment seek to undervalue them; but I confess I am often led to consider this subject with feelings of regret and misgiving, and to ask myself whether the conveniences afforded by the subdivision are not more than compensated by the disadvantages that accompany them. Undoubtedly, the constantly quickening pace of the march of science makes it every year increasingly difficult for those whose lives are devoted to the active and engrossing prosecution of research in one special department of inquiry to keep in touch even with the broader features of the advance that is being made in other departments. We cannot be surprised that a man whose whole energies are absorbed in one line of study should neither care to listen to, nor to burden his library shelves with, papers in other lines, full of technicalities which he has had no time to master, and written, therefore, in a language which to him is more or less unintelligible. In this way the workers in widely separated fields of inquiry tend to be more and more completely isolated from each other.

But surely such isolation is a defect in our organisation which deserves serious attention. It cannot be for the general good of scientific progress that the eyes of an investigator should seldom or never be lifted from his own field of work, nor his ears be open to the reports of the advances made in other fields that lie outside his immediate interests. The wider his outlook, the greater must obviously be his capacity for judging of the general bearings of discovery in his own domain on other departments of research, and the broader and more intelligent will be his sympathies with the whole range of activity on which the continued march of natural knowledge depends.

The Royal Society is still the one great institution in this country which draws its members from the cultivators of every branch of science, and freely opens its publications to receive their communications of observation and discovery. It should thus be specially fitted to bring the workers on the two sides of science, physical and biological, into touch with each other. It has recognised, and in various ways endeavoured to discharge, its duty in this respect. In its Croonian and Bakerian lectures it has given to the world many masterly expositions of the progress of research in different branches of inquiry. It has likewise provided, by one of its standing orders, for occasional meetings devoted to the discussion of papers of general interest specially prepared for the purpose. Nevertheless, it may be urged that some more frequent and effective procedure might still be devised to lessen the evils of isolation and to make the work that is in progress in one section of the scientific domain more comprehensible in the others. It is futile to find fault with the technicalities of a science. These are its symbols and language with which its students cannot dispense; but without trying to provide for all the needs of the "man in the street," it is often possible to give the gist of an observation or a discovery in simple words that will convey a definite conception of what has been observed or discovered; and thus a subject which, when expounded in brief technical phraseology, repels men of another science, may yet be made interesting and suggestive to these same men.

It may be worthy of consideration whether in those branches of science which, having special societies of their own, are seldom represented by papers at our meetings or in our publications, some of their cultivators might not be invited from time to time to bring before the society reports of recent advances in their different fields of research. Would it not be practicable, for example, to find among the many distinguished chemists in our ranks a few who would be willing to present occasionally at our meetings, in language intelligible to a general audience of scientific men, an outline of the latest progress, present condition, and future problems of some section of their great science?

But, above all, there is an aspect of scientific thought which, although fully recognised by the early fathers of the Royal Society, is too apt to be overlooked amidst the engrossing pressure of modern research. I allude to the philosophy of science. At intervals in the progress of scientific inquiry it is desirable to look at the subject from the philosophical side, and to seek for a correlation and synthesis of the various processes of nature which discovery has revealed. The mental vision required for this quest is not given to more than a few gifted minds; but we can count among the number of our fellows more than one admirably qualified by wide knowledge and rare powers of generalisation to present a connected view of the broader bearings of discovery in the scientific domain in which each is a master. Memoirs of this type will, I trust, continue to be laid before us, perhaps at more frequent intervals, thus upholding the renown of our Philosophical Transactions and sustaining the prestige of the society.

Had the Royal Society no other duties to discharge save those in connection with the preparation of its publications, it would, like other scientific societies, have work enough on hand fully to occupy its time and absorb its resources; but the performance of these duties fills up only part of its programme. In this respect the society differs from other learned bodies. It possesses a large and diversified field of activities about which most, even of our fellows, know little, and the world outside still less. Our Yearbook, indeed, presents a formidable list of the public functions which have devolved upon the Royal Society. That list, however, conveys no adequate idea of the varied and even exacting character of some of its items; but, over and above the functions therein enumerated, others of a less public kind make large demands upon the time and thought of many of our fellows.

For many years past the Royal Society has acted as a kind of board of advice to the Government of the country in matters wherein scientific knowledge is required. In this informal capacity the society has been requested to undertake the conduct of many inquiries in the public interest. It has been likewise entrusted with the administration of funds voted by Parliament for the promotion of investigation.

Requests are not infrequently made to the society by different Government departments for advice or cooperation in matters wherein expert scientific knowledge is required. For years past we have had a tropical diseases committee, which, in association with the Colonial Office, has been carrying on investigations into the nature and prophylaxis of some of the maladies incident to the human and animal populations of our colonies and protectorates in warm climates. A commission dispatched by this committee to Uganda has for some time been at work, under Sir David Bruce, studying the decimating scourge of sleeping sickness, while another commission, under the same committee, is busy in London searching experimentally for some drug that may be effective in the treatment of that terrible disease. A few years ago, at the joint instance of the War Office, Admiralty, and Colonial Office, we dispatched a commission to Malta to investigate the peculiar fever which had for so long a time reduced the effective strength of our garrisons and fleets in the Mediterranean. The observers were fortunate in soon discovering the source of the disease, and were able to point out the steps to be taken to cope with it. The result has been that this serious malady has now been almost entirely banished from the hospitals of Malta. At present another committee of the society is engaged, at the request of the Home Office, in studying the disease known as glass-workers' cataract. The India Office likewise applies to us for advice, and we have an "Indian Government Advisory Committee" and an "Observatories Committee," the duty of which is to consider the reports of various public departments in the great dependency, and to offer suggestions towards the improvement of their scientific operations.

Although the Royal Society administers annually a considerable sum of money, by far the largest part of the disbursements is ear-marked for various special applications, and cannot be employed for other objects. So far, indeed, as its general purposes are concerned, the society cannot be regarded as adequately provided. For nearly two hundred and fifty years it has continued to hold aloft the torch of science, but the constantly augmenting demands of modern progress make its task increasingly difficult of satisfactory performance. I have referred to the growing cost of our publications, and there are other parts of our organisation wherein the development of our work is hampered by the lack of funds. Men of science are seldom rich; it is therefore all the more gratifying to be able to record examples of the continuous generous liberality of our fellows; but it is hardly from our own ranks that we can look for any substantial addition to our resources. Perchance in the general community there may yet be found some men who may be led to see that, besides the various laudable objects that have hitherto claimed their care, the advancement of science is likewise an important public and educational interest, and that benefactions are not unworthily bestowed in enabling the Royal Society adequately to maintain the great work which it has inherited from the past.

MEDALLISTS, 1909.

Copley Medal.

The Copley medal is this year awarded to Dr. George William Hill, For.Mem.R.S. Now that Simon Newcomb is no longer with us, Dr. Hill occupies, beyond challenge, the first position in the great subject of dynamical astronomy.

His processes are not only marked by extraordinary originality, the result of high mathematical genius, but also in every case his methods and researches are directed towards practical astronomical ends. His supreme work is probably contained in his researches on the theory of the moon's motion, which has remained the great problem of gravitational astronomy ever since the time of Newton. Here his introduction and development of the principle of disturbed periodic orbits has given an entirely new direction to the science, culminating recently in the lunar tables of E. W. Brown, which mark an epoch in the practical side of the lunar theory.

This work of Hill has been fruitful in new advances in many directions. His ideas have given rise, as developed by Poincaré and other investigators, to new departments of abstract mathematical analysis, while in the hands of Lord Rayleigh they have shed light on important and difficult problems of general mathematical physics.

His collected works have recently been published by the Carnegie Institution of Washington in four quarto volumes; the importance of their contents can hardly be overestimated. M. Henri Poincaré, in his introduction to these volumes, described Hill as "une des physionomies les plus originales du monde scientifique américain."

Astronomy owes to him new theories of the motions of the systems of Jupiter and Saturn, to which the whole of vol. iii. of his works is consecrated.

His shorter papers deal with nearly every problem in the lunar and planetary theories, with mathematical geodesy, and other subjects. All his work is characterised by its original points of view combined with practical aims, by maturity of thought, and high suggestiveness. It forms an index of the simplicity and aloofness of its author, who has been one of the main ornaments of astronomical science for more than a generation.

Royal Medals.

One of the Royal medals has been awarded, with the approval of His Majesty the King, to Prof. Augustus Edward Hough Love, F.R.S., in recognition of his numerous and important contributions to mathematics, and especially to mathematical physics. He has written many valuable papers on various branches of hydrodynamics, in particular on the theories of jets, of vortex motion, and of revolving gravitating masses of liquid. He is the author of a work on "Elasticity," now in its second edition, which is highly appreciated at home and abroad, and ranks as the standard treatise on the subject. In this he has incorporated various valuable researches of his own, which have appeared in the Philosophical Transactions and elsewhere. He has further investigated closely the circumstances of wave-propagation in air, in elastic solids, and in the electromagnetic medium, and has examined in particular the phenomena which present themselves at wave-fronts when the motion is discontinuous. More recently he has published remarkable papers on terrestrial physics, including a speculation on the origin of the present distribution of land and water, and an investigation of the precise extent of the inferences which can be drawn as to the internal constitution of the earth from the observed *data* relating to the heights of ocean tides of long periods, the lunar disturbance of level, and the approximate period of the small movements of the Pole over the earth's surface.

His Majesty has likewise approved of the award of the other Royal medal to Major Ronald Ross, F.R.S.

The name of Major Ross has become widely known on account of the important investigations which he has carried out on the life-history of the malarial organism and the means of preventing malarial infection. Following up a clue indicated by Manson, he began, in 1895, at Secunderabad, in India, in circumstances which entailed much difficulty and many delays, an investigation as to whether the malaria parasite, discovered by Laveran, passes part of its life-history within the body of a biting insect. After more than two years of fruitless experiments Ross discovered a stage of the human malaria parasite in the tissues of a mosquito (Anopheles) which had been allowed to feed on the blood of a malarial patient. In 1898 he proceeded to work out in detail the life-history of a malarial parasite found in sparrows and larks in India. He traced the complicated stages in the development of this parasite from its inception into the stomach of a gnat (*Culex fatigans*) which feeds on the blood of these birds to its passage back into their blood through the secretion of the poison gland of the insect. At the same time he furnished conclusive experimental proof of the part played by the insect in propagating the infection. These fundamental observations have been confirmed and extended in various directions by other observers, both in the British Empire and elsewhere.

As a practical consequence of the discoveries of Ross and those who have followed in his footsteps, and of his own unceasing exertions and further investigations during the last few years, scientifically directed measures for the prevention of malaria have been initiated with striking success in many fever-stricken districts all over the world, and particularly within the British Empire. His investigations have also inspired similar work on the spread, by means of mosquitoes or other biting insects, of other formidable diseases, with the result that effective measures have been devised for preventing the spread of these diseases also.

Davy Medal.

The Davy medal has been awarded to Sir James Dewar, F.R.S.

Sir James Dewar has been a pioneer in the study of very low temperatures, their production, applications, and effects.

For many years he has worked continuously in this difficult domain, and his investigations have resulted from time to time in such achievements as the solidification of oxygen, the liquefaction of fluorine, and the liquefaction and solidification of hydrogen. His improvements in technique have been fundamental. By the construction of vessels in which thermal convection is avoided by the presence of a vacuous layer in their walls, he has enormously simplified the retention and manipulation of matter at very low temperatures. His application of the absorbent effect exerted on gaseous materials by charcoal at low temperatures has placed in the hands of chemists and physicists a most convenient and important method, not only for the production of high vacua, but also for the rapid separation of the constituents of gaseous mixtures. The modifications in the properties of matter at very low temperatures have been investigated, and remarkable results obtained, including the earliest exact investigations, jointly with Prof. Fleming, on the electric properties of insulators and of metals and alloys. The determination of the properties (critical points, boiling points, &c.) of refractory gases at very low temperatures has involved the practical downward extension of absolute thermometry, with the result that temperatures in the neighbourhood of the absolute zero can be determined correctly to within a degree. Lastly, recent measurements of the rate of formation of helium from radium salt, specially purified by Sir T. Edward Thorpe for his recent atomic weight determination, have provided exact molecular data, throwing light on the nature of the spontaneous disintegration of that very remarkable substance.

Hughes Medal.

The Hughes medal falls this year to Richard Tetley Glazebrook, F.R.S.

Dr. Glazebrook has for many years been closely identified with the construction, testing, and evaluation of electrical standards. Not only has he published important memoirs on these subjects, but, as secretary for a very long period of the Electrical Standards Committee of the British Association, and more recently as director of the National Physical Laboratory, he has taken a leading and responsible part in this type of scientific work and in conferences of international importance. It is thus specially fitting that he should be the recipient of the Hughes medal.

The anniversary dinner was held at the Hotel Metropole on Tuesday evening. Sir Archibald Geikie occupied the chair, and a large number of fellows and distinguished guests was present. In proposing the toast of "The Royal Society," Mr. Butcher, M.P., remarked that organised science presents the most signal example of cooperative enterprise in the things of the mind. Modern scientific research demands a host of humble labourers in every field. The hewers of wood and the drawers of water are as necessary as the men of genius. Like the builder of a mediæval cathedral, the obscure worker in the laboratory adds his stone to the fabric, and passes from sight; the individual is effaced, and the structure that slowly rises is the collective achievement of many forgotten workers and even of many generations, guided, however, by a few master minds. While art and literature bear the stamp of permanence, the movement of the sciences produces another kind of effect—that of progressiveness and limitless expansion. Yet, in spite of this irresistible forward movement, the man of science, like the artist, is aware that the ideal may still escape his grasp, and that the quest of truth still remains the search for something that must ever be pursued, that ever recedes, and never can be wholly attainable.

Replying to the toast, the president said that at its foundation every side of intellectual life seems to have been represented in the society. The non-scientific elements which so preponderated at the start were gradually reduced as years went on, but a wide and liberal view of the claims of admission continued to be taken, and the more distinguished in each generation in affairs, in literature, and in art were elected as fellows. This custom is still kept up, but with increasing stringency, until now the number of such persons is limited to two in every two years. There are some fellows who believe that the general interests of the society would be promoted by the introduction of a larger leaven of culture which is not scientific.

The Japanese Ambassador, responding to the toast of "The Guests," said it is barely forty years since Western science was transplanted into Japan on anything like an adequate scale. For the progress being made Japan owes an immense debt of gratitude to the scientific men of the West, and particularly to scientific men of Great Britain.

NOTES.

The meeting of the Royal Irish Academy on Tuesday, November 30, was occupied by a commemoration of Charles Darwin, the date nearly coinciding with that of the publication of "The Origin of Species" fifty years before. The president, Dr. F. Tarleton, opened the proceedings, and the following short addresses were given on the influence of Darwin's work:—geology, Prof. G. A. J. Cole; geographical distribution of animals and plants, Dr. R. F. Scharff; zoology, Prof. G. H. Carpenter; botany, Prof. T. Johnson; anthropology, Prof. A. F. Dixon.

The Washington correspondent of the *Times* announces that a recommendation is to be submitted to the Department of Commerce and Labour by the Bureau of Fisheries that the Government should bring about an international conference for the formulation of an international marine game law to protect from extinction seals, whales, walruses, and other sea mammals. The countries which would be invited by the United States to send representatives to the proposed conference are Great Britain, Russia, and Japan.

The council of the Child-study Society has approached Prof. Karl Pearson, F.R.S., to assist its efforts to advance scientifically our knowledge of child-life. Prof. Pearson has drafted a schedule for studying the factors influencing the social life of the child, which he desires to have filled in by heads of families or by teachers intimate with families. The number in the family need not be large, but particulars of father, mother, and at least two children are required. The schedules are being distributed through branch secretaries of the Child-study Society, but it may be difficult in a short time to secure the number requisite to make the subsequent investigation by Prof. Pearson worth while. The society appeals to members of learned societies and to professional men and women to assist the scheme by applying for a copy of the schedule and filling in the particulars. Copies can be obtained from the secretary of the Child-study Society, London, 90 Buckingham Palace Road, London, S.W.

PROF. SORLEY, in his paper on "The Interpretation of Evolution" communicated to a meeting of the British Academy on the fiftieth anniversary of the publication of the "Origin of Species," drew a distinction between inorganic and organic evolution which appears to belong rather to the material forming the subject of the process than to the process itself. It is perhaps true that, as he says, physiologists are on the whole less satisfied now than formerly with the adequacy of the physico-chemical explanation of vital activities; but they have not all abandoned the idea of gaining a more profound insight than at present into the nature of life, nor do they anticipate that any increase of knowledge will tend to exclude vital phenomena from the domain of natural law. That the history of vital activity is in a true sense teleological may be readily conceded, and it is possible that Prof. Sorley is right in holding that the whole course of evolution can only be interpreted "by means of the conception of conscious purpose." Such contentions, however, belong to a domain which is outside that of science.

MR. BALFOUR'S Romanes lecture, delivered at Oxford on November 24, was couched in his happiest vein of genial scepticism. The chief function of literary and artistic critics in all ages has been, he said, to sweep away the rubbish of their critical predecessors. No standard of æsthetic excellence has been found to be permanent; attempts to find an ethical or religious end to art, though not valueless, are independent of the critical question. It is true that in the present age there is a superficial appearance of unanimity as to what is and what is not a successful work of art, though a man of genius like Matthew Arnold or Ruskin will occasionally kick over the traces; but in the history of artistic criticism this unanimity is not to be found. The great Gothic builders were only restrained by considerations of time and money from demolishing the work of their predecessors. Training and study are undoubtedly sources of subsidiary æsthetic pleasure, but the increase of powers of discrimination may be accompanied by a waning of æsthetic sensibility. Are we not, then, obliged to regard æsthetic emotion as a mere accidental by-product of evolutionary process? No assistance is afforded by the instinctive efforts of the popular philosophy to press morals, religion, utility, or progress into the service, nor can satisfaction be obtained out of the metaphysical treatment of the subject; but there remains the consideration that, besides the class of emotions to which the æsthetic sense belongs, there is another class, practical rather than contemplative, at the head of which are the loftiest feelings—love and devotion—of which human nature is capable. These practical emotions, Mr. Balfour thinks, are recalcitrant at present to any logical or philosophical treatment. Why, then, should we quarrel because we can at present find no adequate philosophy of the æsthetic emotions?

THE eighth International Zoological Congress is to be held at Graz (Austria) on August 15–20, 1910, under the presidency of Prof. Ludwig von Graff. The first general meeting of the congress will be held in the afternoon of August 15 in the great Stephaniensaal of the Steiermärkische Sparkasse, and further similar meetings the next and every morning up to and including August 19. Sectional meetings will be held on each of the four afternoons from August 16–19 in the Natural History Institute of the University. A meeting of the nomenclature committee and the committee for the Concilium Bibliographicum has been arranged for August 16 in the Zoological Institute, and the permanent committee of the congress will meet at the same place on August 17 to consider the place of meeting for 1911. Two lantern lectures will be given during the evenings of August 16 and 17 on "Die Steiermark" (Styria), and "The Austrian Riviera, Bosnia, Herzegovina." In addition to short excursions during the late afternoon of the earlier days of the congress, longer journeys have also been arranged. Among the more ambitious excursions may be mentioned:—to the Erzberg and the Leopoldstein See on August 20, to Triest on August 21, and to Dalmatia by special steamer from August 22–27. A banquet will be given by the congress on August 19 to the honorary members, members, and participants. Not only professional zoologists, but all persons interested in zoology, may take part in the congress, which covers the whole field of biology in the widest sense, including, for instance, palæozoology, hydrography, and marine biology. All inquiries relative to the congress should be sent to the Präsidium des VIII. Internationalen Zoologen-Kongresses, Universitätsplatz 2, Graz (Österreich).

WE have to acknowledge the receipt of a copy of No. 62 of the Hull Museum Publications, in which various additions to that museum are recorded; also of vol. v., No. 2, of the *Museum News*, the first article in which is devoted to an account of an exhibition of mediæval architecture in the Brooklyn Museum.

ACCORDING to the October number of the *Victorian Naturalist*, it is proposed to erect in Sydney a statue or some other appropriate memorial to Sir Joseph Banks, who has been called the "father of Australia." In order to awaken interest in the matter, Mr. J. H. Maiden, the Government botanist of New South Wales, has written a full and elaborate life of Banks, and has generously promised to hand over the profits on the sale of the volume to the memorial fund.

IN discussing a new digger-toad from Manchuria in the September issue of the Proceedings of the Academy of Natural Sciences of Philadelphia, Mr. T. Barbour takes exception to the emendation of the barbarous generic name Kaloula to the more classical Callula. Seeing that the emendation was made by Dr. Günther and accepted by the late Prof. Cope, and subsequently by Mr. Boulenger (in the official British Museum Catalogue), it is surely a little strong to write that "*Callula*, a more recent emendation, has no standing in nomenclature." Günther, Blanford, and Boulenger have all seen fit to amend (or accept amendments of) ill-spelt or ill-formed zoological names, and it scarcely becomes their juniors to say they were not justified in so doing.

IN the first portion of an article on the nuptial habits of the black-cock in Scandinavia and England, published in the November number of the *Zoologist*, Mr. Edmund Selous alludes to certain very definite statements made by a Swedish forester to the effect that these birds are in the habit of making burrows for themselves beneath the snow, in which they remain for considerable periods during severe weather. Although each bird makes its own tunnel, it seems probable that the tunnels may often open into a common chamber, where several black-cock may remain in company for the sake of warmth. The capercaillie, on the other hand, has no need for such shelters—and perhaps food-supplies—as the pine needles which form its food are always obtainable in abundance.

The November number of the *American Naturalist* opens with the first part of an instructive article, by Mr. Newton Miller, on the life-history and habits of the American toad, this article being written to illustrate the proper way of studying common American animals from the point of view of their position as active forces in the economy of nature. After devoting a considerable amount of space to the breeding-habits and development of the species, the author makes the (to us) novel observation that "toads are more numerous in and about towns than elsewhere. Very rarely is a toad seen in a large field under cultivation. Only fifty toads were seen during a whole season on one thousand acres of farming land in central Indiana. This scarcity may be accounted for by two factors, *i.e.*, first that pasturage and tillage kill the toads, or, secondly, that the extensive drainage has exterminated the toad by depriving it of breeding places."

Mutation in Ceratium, a protozoan common to fresh and salt water, forms the subject of No. 13 of vol. lii. of the Bulletin of the Museum of Comparative Zoology at Harvard College. After describing the mutations observed, the author, Mr. C. A. Kofoid, states that the most important fact in the phenomena is the abrupt and complete change in form in a line of descent in a single generation, or at most in two generations, of organisms asexually produced. The change is recorded in fixed skeletal parts which clearly show the transmutation in shape, while the accessory phenomenon of chain-formation enables the line of descent to be accurately traced. These changes do not give rise to new types, "but old well-known types give rise suddenly to others old and well known, or at least previously known. The particular category to which these types are referred, species, subspecies, varieties, or forms, is a subordinate matter. . . . The fact remains that like gives rise to unlike, that the descendants differ profoundly from the ancestral type."

Prof. Hickson and Mr. Wadsworth give an interesting account in the *Quarterly Journal of Microscopical Science* (vol. liv., part ii.) of their observations on *Dendrosoma radians*. This remarkable Acinetarian occurs in abundance on the stems of Cordylophora in the Bridgewater Canal near Altrincham, and supplies were also obtained from Birmingham. The authors give a detailed account of the minute structure of the adult and the formation and development of the ciliated gemmule. They find that the so-called "external buds" described by Saville Kent are really epizoic Acinetarians of the genus Urnula. The phenomena of conjugation have not yet been observed.

The *Quarterly Journal of Microscopical Science* (vol. liv., part ii.) contains a continuation of Mr. Goodrich's well-known researches on the structure of the excretory organs in Amphioxus. Mr. Goodrich brings forward what appears to be very conclusive evidence in favour of his view that the nephridia of Amphioxus do not open, as Boveri has supposed, into the cœlom, but end blindly at their inner extremities. He maintains the homology of these organs with the nephridia of Annelids and Platyhelminths, and not with the kidney tubules of the Craniata, and gives a partial, but very interesting, account of their development. He has examined the sections upon which M. Legros based his conclusions as to the origin of the nephridia from the cœlomic epithelium, but does not agree with this author on this important point. We are left to conclude that the nephridia of Amphioxus are probably ectodermal in origin, although the question is not discussed in detail at present. The paper also deals with the structure known as Hatschek's nephridium, and the discovery of solenocytes in this organ by Goldschmidt is confirmed. It appears to be a true nephridium, homologous with the posterior nephridia, but the fact that it opens into the alimentary canal (externally; it has no internal opening) remains unexplained. We must also direct attention to the valuable criticism of Prof. Hubrecht's views on the early ontogenetic phenomena in mammals, by Mr. Richard Assheton, which concludes the number.

In a pamphlet recently published at Athens under the title of "’Ιωάννης Λαμὰρκ καὶ τὸ ἔργον αὐτοῦ," the author, M. Athanasios E. Tsakalotes, gives a very clear and impartial account of Lamarck's life and work. Passing in brief review the facts and dates of the famous French naturalist's scientific career, he enumerates the various systematic treatises that came from his pen, and enlarges on the evolutionary views which found expression in the "Philosophie Zoologique," published just one hundred years ago. The main points in Lamarck's theory of descent are well brought out—his belief in the continuity of the process, his consequent rejection of Cuvier's theory of successive catastrophes, his doctrine of the inherited effects of use and disuse, and of the direct action of the environment on plants and on the lower animals. The author shows how intimately in Lamarck's mind the facts of adaptation were connected with the problem of evolution; the passage in the "Philosophie Zoologique" on the relation of structure to habit and function in the three-toed sloth might, he asserts, have been written by Darwin himself. That Lamarck's views failed to commend themselves to his scientific contemporaries was, the author thinks, partly his own fault; for the reasons that he was in too great a hurry in reducing his speculations to a complete system, and that he weighted his theory with improbable psychic elements, for example, the alleged influence of individual volition. The author might have added that Lamarck lacked the touch of genius that led Darwin and Wallace to find in natural selection the key to the problem of adaptation.

Mr. Carus-Wilson informs us that he has sent to the Kew Museum the specimen of oak in which stones are embedded, referred to in his recent paper on "The Natural Inclusion of Stones in Woody Tissue," described in Nature of November 25 (p. 117).

The development of the embryo-sac of *Datisca cannabina* forms the subject of an article by Dr. W. Himmelbaur in the *Sitzungsberichte der Kaiserlichen Academie der Wissenschaften*, Vienna (vol. cxviii., part ii.). One division of the embryo-sac mother cell is the rule; otherwise, except for the early disappearance of the antipodal cells, development is normal. The author refutes the possibility of parthenogenesis, but finds that parthenocarpy, *i.e.* the maturation of the fruit without fertilisation of the ovule, may occur.

A study of trichomes as hereditary characters in a few pure and hybrid species of Juglans, Œnothera, Papaver, and Solanum, is described by Dr. W. A. Cannon in Publication No. 117 of the Carnegie Institute of Washington. It is apparent that the trichomes in these cases are not allelomorphs; in fact, they vary in size as much according to their position on the leaves as they do for different species. The development of the hairs on the leaves was also investigated for the species of Juglans, and found to be consistently uniform except in a single type observed in an F_2, or second hybrid generation.

The current number of *Irish Gardening* (November) opens with an account, by the Hon. Vicary Gibbs, of a few of the shrubs collected by Mr. E. H. Wilson during his last visit to China. About forty species of Rubus have been introduced, chiefly on account of their decorative foliage and stem colouring; also a number of new species of Hydrangea, Ribes, and Vitis. New climbers are furnished by the genera Clematis and Lonicera, of which *Clematis Pratti* and *Clematis souleana* receive special mention. A short report is given of a meeting held in Dublin by the Irish Forestry Society with the object of promoting an annual November "Arbor" week; the economic importance of forestry and the former extent of Irish forests formed the subject of addresses. A novel plan is mentioned in a note of etherising the roots of fruit trees to retard the blossom and so save it from being destroyed by spring frosts; the experiment is said to have been successful.

Owing to the custom which prevails so largely in Germany of making presents of plants at Christmas and on other auspicious occasions, there is a great industry in forcing plants, notably lilacs and cyclamen. As a consequence of this unnatural treatment diseases appear, or become more malignant, and in this connection a brochure by Dr. H. Klebahm, dealing with diseases in lilacs, has been recently published. A bacterial disease of the branches or leaves caused by *Pseudomonas Syringae*, and other leaf diseases due to a Heterosporium and Botrytis, are referred to, but the main purpose is to give the details of a new disease, traced after considerable trouble to a Phytophthora. Full details of the life-history, which is similar to that of *Phytophthora omnivora*, have been worked out.

We have received from the Michigan State Agricultural College Experiment Station several bulletins dealing with subjects of practical interest. The construction of silos of wood and of cement is described, the latter material being found especially satisfactory. The number of silos in Michigan is steadily increasing; green maize is generally used, either alone or mixed with field peas, cow peas, or soy beans, &c. A description is given of the methods used in treating pigs for the prevention of hog cholera by injection of the appropriate serum; good results are said to be obtained. Another bulletin deals with the feeding of farm horses during winter time, a highly important economical problem. Several rations are suggested, and the cost is worked out in each case.

The report of the Botanic Station Agricultural School and Experiment Plots, St. Lucia, is a record of continued progress. The soil under cultivation is generally very fertile, and as the population is not large the means of subsistence is easily gained by the natives. In consequence, the methods of cultivation are not very advanced, and there is abundant scope for the work of the agricultural instructors. Attempts are being made to develop the cultivation of Sea Island cotton, and also to assist the sugar industry. Improved methods of dealing with cacao and limes are being worked out, and the various pests submitted to examination. A number of rubber trees and mangoes have been distributed among the planters from the station.

The bird problem in relation to agriculture is discussed in a recent number of the *Journal of Agriculture of South Australia*. Among insectivorous birds recommended to be encouraged are the wrens (*Malurus cyaneus*), the flycatchers (*Rhipidura tricolor*, *Sisura inquieta*, *Micraeca fascinans*), the robin (Petrœca, sp.), the swallows, the thrush (*Collyriocincla harmonica*), the pipit (*Anthus australis*), the catbird (*Pomatorhinus superciliosus*), and the yellow-rumped tit (*Acanthiza chrysorrhoa*). On the other hand, the sparrow and the starling do great damage, and the advisory Board of Agriculture has recommended that stringent methods of dealing with them should be made compulsory.

In continuation of his general discussion on the earthquakes of the Philippines, noticed in Nature of October 28 (vol. lxxxi., p. 527), the Rev. M. Saderro Masó has undertaken the study of the different seismic regions of the archipelago. His first paper deals with the earthquakes of the Batanes Islands, a group in the extreme north, and only about 200 kilometres from Formosa. In the central island of Batan forty-nine earthquakes were recorded in the six years 1903–8, May and June being the months of greatest frequency. None of these shocks exceeded the degree of intensity 5 of the Rossi-Forel scale. Father Saderro Masó discusses the interesting question whether the Batanes Islands are more closely related seismologically with Formosa or Luzon, and, though the evidence is not very complete, concludes in favour of their connection with the latter and more distant island.

Mr. T. Sheppard, the curator of the Hull Museum, continues his useful series of catalogues of the collections under his charge, which are issued at the nominal price of one penny each. The last numbers are devoted to an account of a large collection of Roman antiquities from South Ferriby, in North Lincolnshire, and of a number of Anglo-Saxon vases. These publications are issued in cooperation with the Hull Scientific Field Naturalists' Club, which is doing excellent work in cataloguing the fauna and flora of Yorkshire. The second part of its Proceedings for the current year is largely devoted to an account, by Mr. T. Stainforth, of the spiders, harvestmen, and pseudo-scorpions of East Yorkshire.

The common horseradish (*Cochlearia armoracia*, L.) has been described by Darwin and others as a plant which practically never produces seeds. M. J. Brezezinski contributes to the Bulletin of the Cracow Academy of Sciences, No. 7 (1909), some interesting experiments on this point. He adopted two plans of favouring the production of seeds—grafting and an annular incision round the root. The former plan was a failure, but the latter led to the production of a good number of seeds, some of which germinated and have grown up. These seedling plants belong to two widely differing types, of which illustrations and descriptions are given.

A paper on the decimal system of numbers is contributed to the *Popular Science Monthly* for November by Dr. L. C. Karpinski. It contains a historical account of the Babylonian, Roman, Greek, Hindoo, and Arabic systems. A necessary conclusion is that improvements in the system of numeration have been slow to obtain adoption. Even at the present day France does not possess a decimal system of numeration, the use of 20 as a base being still preserved in numbers above 60, a system which, we are told, is of Semitic origin, and exists also among certain Pacific Coast tribes. It exists also in Wales. As a further illustration, the author refers to the slowness of the United States and England to adopt the metric system.

The principal of the Belfast Municipal Technical Institute has drawn up a valuable series of notes on the method of conducting experiments set in laboratory courses of experimental science. The guidance offered is intended to secure a desirable amount of uniformity in the conduct of the various laboratory classes in the institute. It is, we notice, made clear that the teachers in charge of the laboratories concerned are at liberty to modify the suggested scheme to meet their special needs. The notes should be of assistance to young demonstrators who are gaining experience as indicating what a successful teacher has found to be a good plan of procedure, but any slavish copying of a hard and fast routine would be undesirable in most cases. The notes have been printed for distribution among the staff at Belfast.

THE *Physikalische Zeitschrift* for November 10, and part xx. of the *Berichte der deutschen physikalischen Gesellschaft*, are both devoted to reports of the physical papers read at the Versammlung deutscher Naturforscher held at Salzburg in September. The former periodical gives, in addition, reports of the discussions following the reading of the papers. An afternoon sitting was devoted almost entirely to papers on the problems which arise in the treatment of radiation and in the building up of electrodynamics on the principle of relativity. Prof. Sommerfeld discussed the composition of velocities, and Dr. M. Born the dynamics of electrons on the theory of relativity. Prof. Einstein gave an interesting account of the development of our views of the origin and constitution of radiation, an account which will be of special value to those who are looking forward to the appearance of Sir Joseph Larmor's recent Bakerian lecture.

MESSRS. ELLIOT BROTHERS are making an accelerometer and gradient measurer, devised by Mr. H. E. Wimperis, which is both ingenious and simple and is free from disturbance by motions of any kind, except that of acceleration in one direction or of tilting in the same direction. Two vertical spindles are geared together so as to run in opposite directions, and they are each eccentrically weighted, and the weights are so placed that their motions in the direction marked upon the instrument are the same and conspire in their effect, while those transverse to this direction are opposite and neutralise each other's effect. One of the spindles carries a copper disc damped by a permanent magnet, an index moving over the scales of acceleration and gradient, and a controlling hair-spring. Such a combination is unaffected by rotational movement or by rotational acceleration of the instrument about any axis whatever; it is also unaffected by transverse or vertical motion or acceleration, or by longitudinal steady motion. It is therefore affected by longitudinal acceleration or by fore and aft gradient alone. As either fore and aft tilting and fore and aft acceleration are of necessity both operative, it is impossible merely by taking a reading to tell how much of the deflection is due to each if the two causes act simultaneously. The user is therefore instructed how to arrange that one of the effects is zero, or, if they both act together, to determine one by an independent observation. A large number of illustrations of the utility of the instrument are described, including power of engine, efficiency of brakes, friction when running idle, and measurement of gradients.

WE have received the first part of Dr. Ludwig Koch's "Pharmakognostischer Atlas" (Leipzig: Gebruder Borntraeger), which is intended to form a supplement to the recently completed work by the same author on the microscopical analysis of drug powders. The atlas will deal mainly with the crude drugs of the German Pharmacopœia, and will contain illustrations and descriptions of sections cut in various directions, the illustrations being sufficiently extensive to show, not only the nature of the elements that occur, but also their relative quantity. Judging from the first part, the figures, so important in a work treating of structural details, will leave nothing to be desired in clearness or accuracy, and the descriptions, though minutely detailed, will be readily intelligible. The work promises to be one of the most valuable of its kind, and to be indispensable to everyone interested in the anatomical structure of drugs.

MESSRS. J. J. GRIFFIN AND SONS have issued their list of chemicals manufactured by C. A. F. Kahlbaum, of Berlin. In comparison with their previous list there has been an expansion from 79 to 95 pages. As compared with the German price-lists of Kahlbaum and Schuchardt, the present list shows an increase of price amounting, in the case of typical materials, to about 35 per cent., but as the English prices include cost of freight, bottles, and packing, the difference on small orders is not excessive, and there can be no difference of opinion as to the advantages gained by having a stock of these materials available in London for immediate use.

THE Journal of the Chemical Society for October contains an interesting paper by Mr. R. W. Gray and Mr. F. P. Burt on the atomic weight of chlorine. The work is divided into three parts—a revision of the density of hydrogen chloride, a re-determination of its volumetric composition, and a study of its compressibility at 0° between the limits 780 mm. and 150 mm. The density was measured by an ingenious application of the condensing action of charcoal cooled by liquid air, as suggested and used by Dewar and Jones. The gas to be examined was condensed by liquid air, carefully purified by fractional distillation, and transferred for measurement of volume to a flask of 460 c.c. capacity surrounded by ice and distilled water, and connected to a manometer; for measurement of weight it was connected to a charcoal bulb having a capacity of only about 20 c.c.; when cooled with liquid air the charcoal absorbed the whole of the hydrogen chloride, leaving a vacuum both in the weighing and measuring bulbs, and by closing the bulb by a stop-cock its weight could be determined at atmospheric temperatures. The average density, after correcting for adsorption of gas by the walls of the measuring bulb, was found to be 1·63915 grams per litre. The volumetric analysis, carried out by measuring the volume of hydrogen set free by the action of aluminium on the gas, gave a mean volume of 1·00790 vols. hydrogen from 2 vols. hydrogen chloride. Combined with Morley's value for the density of hydrogen, the authors' own value for the density of hydrogen chloride, and Morley's value for the ratio of oxygen to hydrogen, this gave the atomic weight 35·459. A comparison of the densities of hydrogen chloride and oxygen, both corrected for deviations from Boyle's law, gave $Cl=35·461$. The mean value $Cl=35·460$ coincides exactly with the mean of seven recent determinations ranging from 35·452 to 35·466, and there can be little doubt that the figure is substantially correct.

THE firm of Gauthier-Villars, of Paris, has published the first of a series of volumes projected under the general title "Savants du Jour." The present book deals very appropriately with M. Henri Poincaré, whose work is known to men of science everywhere. The frontispiece to the volume is an admirable portrait of M. Poincaré. The text is divided into seven sections; the first is in the form of a biography, which comprises the discourse by M. Frédéric Masson last January in response to an oration by M. Poincaré when received by the Académie Française, a chronological list of the distinctions conferred upon the subject of the work, and a list of the appreciative articles upon his career which appeared in the French Press. The succeeding six sections are concerned, respectively, with

M. Poincaré's works in mathematical analysis, analytical and celestial mechanics, mathematical physics, and scientific philosophy; his obituary notices of numerous men of science, including the late Lord Kelvin; and his more various writings. Each of the sections dealing with M. Poincaré's scientific work is prefaced by an appreciation by some great authority; thus, that on celestial mechanics is preceded by a translation of Sir George Darwin's address in presenting the gold medal of our Royal Astronomical Society last February. The price of this interesting volume is 7 francs.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN DECEMBER:—

Dec. 2. 6h. Venus at greatest elongation, 47° 18′ E.
,, 18h. Mercury in superior conjunction with the Sun.
6. 10h. 35m. Jupiter in conjunction with the Moon (Jupiter 3° 35′ S.).
12. 7h. 45m. Sun eclipsed, invisible at Greenwich.
,, 19h. 27m. Mercury in conjunction with the Moon (Mercury 0° 3′ S.).
14. 13h. 51m. Uranus in conjunction with the Moon (Uranus 3° 5′ N.).
16. 3h. 10m. Venus in conjunction with the Moon (Venus 2° 50′ N.).
18. 9h. Mercury in conjunction with λ Sagittarii (Mercury 0° 3′ N.).
20. 10h. Saturn stationary.
,, 11h. 56m. Mars in conjunction with the Moon (Mars 5° 0′ N.).
,, 21h. 2m. Saturn in conjunction with the Moon (Saturn 1° 40′ N.).
27. 8h. 30m. Neptune in conjunction with the Moon (Neptune 4° 9′ S.).
,, 20h. 1m. Mercury in conjunction with Uranus (Mercury 1° 43′ S.).

HALLEY'S COMET, 1909*c*.—The following is a further extract from Mr. Crommelin's revised ephemeris for Halley's comet as given in No. 4359 of the *Astronomische Nachrichten*:—

Ephemeris.

1909 (Berlin M.T.)	R.A. (1910·0) h. m.	Decl. (1910·0) ° ′	log *r*	log Δ	Magnitude
Dec. 1·4	4 26·9	+15 52			
6·4	4 6·2	+15 23	0·3775	0·1505	12·4
11·4	3 44·4	+14 45			
16·4	3 22·3	+14 4	0·3527	0·1340	12·0
21·4	3 0·6	+13 18			
26·4	2 40·2	+12 28	0·3259	0·1381	11·8

From this we see that the comet is now a little to the west, and south of, Aldebaran, and on December 4 will pass very near to γ Tauri.

According to a note by Mrs. Maunder in the *Daily Chronicle*, Mr. Hollis found the comet a conspicuous object in a 10-inch telescope on November 22, and the Rev. T. E. R. Phillips observed it the same evening, and was still able to see it when the aperture was reduced to 3 inches. Photographs taken at Greenwich on that date showed the comet to be somewhat brighter than the tenth magnitude, *i.e.* about eight times as bright as computed.

OBSERVATIONS OF MARS.—Seven new canals, bringing the total found at the Hem Observatory up to twenty-three, are announced by Mr. Jonckheere in No. 4371 of the *Astronomische Nachrichten*. For two of them, leaving the Cyclopum Lucus and going to Hephæstus and Amenthes respectively, Mr. Jonckheere proposes the names Cepheus and Cassiopeia.

The *Comptes rendus* for November 15 (No. 20) contains three notes dealing with the planet. In the first M. Idrac describes the visual and photographic observations made by him at Meudon during the recent opposition. The photographs were taken in the focus of the 24-inch photographic equatorial, and show a fair number of details, some of which were not visible, or very faint, to the naked eye; the plates used were sensitive to the blue and ultra-violet radiations. On September 20 the edge of the north polar cap was shown clearly on the photograph, and on September 25 extended down to about latitude 55°.

In the second note M. Antoniadi describes the results of thirteen nights' observations made between September 20 and November 9. The most remarkable changes, since the opposition of 1907, appear to be the return of Syrtis Major to the form it had in 1864 and 1877, the re-apparition of Lac Mœris, and the formation of a multiple "island" in the eastern part of the Mare Cimmerium. About fifty "canals" were seen, but M. Antoniadi discusses the meaning of this term before applying it definitely to the features seen. He defines eight types of markings which may be called "canals," and finds that there is no geometrical *réseau* of straight lines intercrossing on the surface of Mars; but across the continental areas there is a structure like a grey marbling, which is too evanescent and intricate to be drawn. A useful chart (Mercator) accompanying the note embodies the features seen at Meudon.

MM. de la Baume Pluvinel and F. Baldet contribute the third note, which describes the photographic researches carried out on the Pic du Midi during September and October. Ordinary plates were used at first, with exposures of 0·1s., but these showed only the polar caps. Later exposures, with Lumière colour filters and various bathed plates, took 6s. to 12s., and show nearly all the details observed visually; the geometrical *réseaux* of fine canals are not, however, to be found on the photographs.

During the recent opposition, M. Kostinsky, using the Pulkowa astrographic telescope, succeeded in obtaining photographs of the two satellites Phobos and Deimos, and now publishes the measures in No. 4369 of the *Astronomische Nachrichten*. The accordance with the ephemeris (based on Struve's elements) is satisfactory, and the photographic magnitudes of the satellites are 11·6 and 12·3 respectively.

PERRINE'S COMET, 1909*b*.—An observation of Perrine's comet, made at Heidelberg on November 20, gave the position at 13h. 0·2m. (Königstuhl M.T.) as 7h. 6m. 20·33s., +15° 31′ 28″ (1909·0), and the magnitude as 14·0 (*Astronomische Nachrichten*, No. 4371).

In No. 4369 of the *Astronomische Nachrichten* Prof. Wolf directs attention to an abnormal decline of the brightness of this object about November 9. On October 11 it was seen with difficulty in the reflector, and on November 6 could not be found visually, although since September 5 it has been observed visually with a 6-inch telescope. A photograph taken with the Bruce telescope on November 9 failed to show any trace of the comet, which must therefore have become enormously fainter.

THE DESIGN OF SPECTROGRAPHS.—All those who are interested in the design and performance of spectrographs, more especially such as are used for radial-velocity determinations, will welcome a paper by Mr. J. Plaskett which appears in No. 4, vol. iii., of the Journal of the Royal Astronomical Society of Canada. As is now generally known, Mr. Plaskett has, since 1905, devoted a great deal of labour to the design of a generally effective instrument, and he has now succeeded in producing a single-prism spectrograph which has proved beautifully effective. Rigidity, temperature control, and optical efficiency have all been provided for, and the instrument can be changed from a one- to a three-prism spectrograph in two minutes without affecting the temperature conditions. Mr. Plaskett gives illustrations and full details of the numerous minor devices and accessories, which it is impossible to reproduce here.

THE ASTRONOMICAL SOCIETY OF WALES.—No. 3, vol. xi., of the *Cambrian Natural Observer*, the quarterly record of the Astronomical Society of Wales, contains several useful notes for amateur observers. Miss Hagerty contributes an interesting article on solar energy, and Mr. Mee asks all Welsh observers to forward to him accounts of any astronomical phenomena they may observe; he gives some useful hints as to what the naked-eye observer may see and should record.

BRITISH ASTRONOMICAL ASSOCIATION.—Messrs. Neill and Co., Edinburgh, have just published, for the British Astronomical Association, a general index of the Journal from vol. i. to vol. xviii. The index has been compiled by Mr. F. W. Levander.

RESEARCHES IN RADIO-TELEGRAPHY.[1]

RADIO-TELEGRAPHY, popularly called wireless telegraphy, has outlived the tentative achievements of its precocious infancy and obtained for itself a settled but important position amongst our means of communication.

This stage, however, has only been reached after a long struggle with experimental difficulties and much labour in analysing the processes involved. As many of these matters are of general scientific interest, it is proposed, during the present hour, briefly to summarise the results of some recent research.

It is well known that the nature of the earth's soil or surface between the sending and receiving stations has a great effect upon electric waves passing over it. If the surface is a very good conductor the wave hardly penetrates into it, but glides over the surface. If it is a poor conductor the wave penetrates into it to a greater extent, and the worse the conductivity the deeper the penetration.

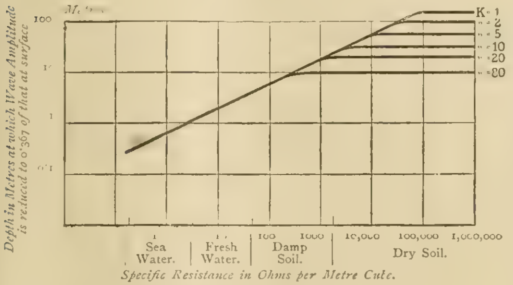

FIG. 1.—Depth of Penetration of Waves 1000 feet in length. (Dr. Zenneck.)

The materials of which the earth's crust is composed, with some exceptions, owe their electric conductivity chiefly to the presence of water in them. They are called electrolytic conductors. Substances like marble and slate, when free from iron oxide, are fairly good insulators. Dry sand or hard dry rocks are poor conductors, but wet sand and moist earth are fairly good conductors. Sea water, owing to the salt in it, is a much better conductor than fresh water. The following table gives some figures, which, however, are only approximate, for the specific resistance of various terrestrial materials in ohms per metre cube. It will be seen that dry sand or soils are of very high specific resistance, and damp or wet sand or clay fairly low.

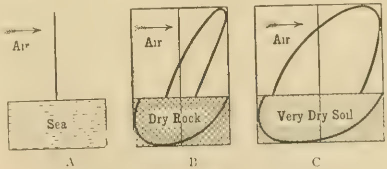
TABLE I.—*Approximate Conductivity and Dielectric Constant of various Terrestrial Materials.*

Material	Specific resistance in ohms per metre cube	Dielectric constant. Air = 1
Sea water	1	... 80
Fresh water... ...	100 to 1000	... 80
Moist earth... ...	10 to 1000	... 5 to 15
Dry earth	10,000 and upwards	... 2 to 6
Wet sand	1 to 1000	... 9
Dry river sand ...	very large	... 2 to 3
Wet clay	10 to 100	... —
Dry clay	10,000 and upwards	... 2 to 5
Slate	10,000 to 100,000	... —
Marble	5,000,000	.. 6
Mercury	0·000001	... infinity

If our earth's surface had a conductivity equal, say, to that of copper, then the electric radiation from an antenna would glide over the surface without penetration. In the case of the actual earth there is, however, considerable penetration of the wave into the surface, and therefore absorption of energy by it.

Brylinski, and also Zenneck, have calculated the depth to which electric waves of such frequency as are used in radio-telegraphy penetrate into the sea or terrestrial strata of various conductivities. For mathematical reasons, it is customary to define it by stating the depth in metres or centimetres at which the wave amplitude is reduced to $1/\epsilon = 0{\cdot}367$ of its amplitude at the surface. I have represented in a diagram some of Zenneck's results calculated for waves of 1000 feet in length, and for terrestrial surface materials of various kinds, conductivities, and dielectric constants (see Fig. 1). You will see that in the case of sea water an electric wave travelling over it penetrates only to the depth of a metre or two, whereas in the case of very dry soil it would penetrate much deeper. Owing to the conductivity of the soil, this movement of lines of magnetic force through it sets up currents of electricity which expend their energy in heat. This energy must come from the original store imparted to the sending antenna, and therefore the wave is robbed of its energy as it travels over the surface.

Dr. Zenneck has discussed mathematically, in a very interesting paper, the effect of the conductivity and dielectric constant of the terrestrial surface, soil or sea, on the propagation of a plain electric wave over it, assuming the radiation to be from an ordinary vertical antenna, and the electric force therefore normal to the earth, and magnetic force parallel to it. The result is to show that there are, broadly speaking, three cases to consider. First, supposing the surface material to be a good conductor, then the wave moves over the surface and penetrates a very little way into it. The electric force in the air over the surface is a purely alternating force vertical to the earth's surface, and the magnetic force is an alternating force parallel to it, and there is very little subterranean electric or magnetic force (Fig. 2, A). This is realised approximately or most nearly in the case of radio-telegraphy over sea water. Secondly, let the earth be assumed to have a very poor conductivity and not a very large dielectric constant, then analysis shows that the electric force in the air has two components, one perpendicular to the earth's surface and one parallel to it, and the resultant is an alternating and a rotating force, the direction of its maximum value being inclined to the surface and leaning forward (Fig. 2, B). The wave-front therefore slopes forward. Also there is a subterranean electric force, showing that the wave is penetrating into the soil, and there is therefore dissipation of energy owing to the conductivity of the soil as the wave travels over the surface. This case is realised when the wave travels over land composed of dry soil having a small dielectric constant. Thirdly, let the earth be a very poor conductor, having a small dielectric constant from 2 to 3, and a specific resistance of about 10,000 ohms per metre cube. For example, very dry earth or sand. Then the investigation shows that the electric force in the air has two components, one parallel to the earth's surface and one perpendicular to it differing in phase, and the resultant is represented by the rotating radius of an ellipse, the maximum value or major axis of which is inclined forward in the direction of the wave motion (Fig. 2, C). At the



$r=1$ ohm per metre cube. $K=80$.

$r=100{,}000$ ohms per metre cube. $K=2-3$.

$r=10{,}000$ ohms per metre cube. $K=1-3$.

r = Resistivity. K = Dielectric constant.

FIG. 2.

---

[1] From a discourse delivered at the Royal Institution, on Friday, June 4, by Prof. J. A. Fleming, F.R.S.

same time there is some penetration of the wave into the earth, and consequent dissipation of energy.

Dr. Zenneck has considered the case of electric waves 1000 feet in wave-length, and has represented the final result by some interesting curves. He defines the effect of the absorption of energy by the soil by stating the distance in kilometres at which the wave amplitude would be reduced by the effect of this absorption to $0{\cdot}367 = 1/\epsilon$ of its amplitude at the sending station, altogether apart from the weakening due to the spreading of the waves out in a hemisphere, which we may call the spherical or space decrease. These curves are plotted to abscissæ representing the specific resistance of the soil (Fig. 3). You will see from this diagram that when a plane electric wave having the above wave-length is propagated over sea water, it would have to travel 10,000 kilometres before its amplitude would be reduced in the assigned ratio, and over fairly dry soil about 100 to 1000 kilometres; but over very dry soil, having a small dielectric constant, only about 1 to 10 kilometres. Also you will notice that the curves rise up again for still higher resistivities. This, of course, is as it should be. All the practical cases lie between two ideal extremes: the case of an infinitely perfectly conducting earth, in which case the waves would not penetrate into it at all, and the other case, an infinitely perfect non-conducting earth, in which the wave would penetrate into it, but would suffer no dissipation of energy. This theory is quite in accordance with practical experience in radio-telegraphy. Every receiving apparatus associated with an antenna of a certain height and kind must be subjected to waves of a certain minimum amplitude to give any appreciable signal. For all lower amplitudes that particular receiving arrangement is perfectly deaf. Now it is a matter of common experience that with a given radio-telegraphic apparatus and antenna it is possible to receive signals for greater distances over sea water than over dry land, and that if the soil is very dry the distance may be cut down very considerably indeed. This is not due merely to the difficulty of making what the telegraphists call a good earth at the sending station, it is due to the absorption of the wave by the earth for the whole distance which extends between the two stations. Hence, also, it is a common experience that when particularly dry weather is succeeded by wet weather the radio-telegraphic communication between two stations on land is considerably improved.

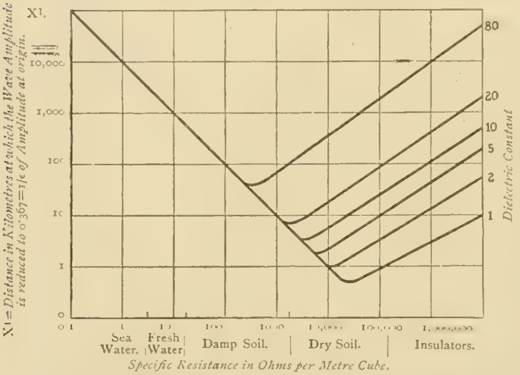


FIG. 3.—Curves showing the Distance in which Electric Waves 1000 feet (300 metres) in length have Amplitude reduced to $1/\epsilon$ by travelling over various surfaces. (Dr. Zenneck.)

The next point in connection with the antenna to be noticed is the means adopted of setting up the oscillations in it. The universal custom at present is to excite oscillations in a reservoir circuit consisting of a condenser and an inductance by means of the spark or arc. If the spark method is used, then the condenser is one of relatively large capacity, and the inductance is kept small. If the capacity is measured in electrostatic units, and the inductance in electromagnetic units, the ratio of capacity to inductance may be something of the order of 5/1 or even 20/1. In this case the condenser is charged by means of an induction coil or transformer, and discharged across a spark-gap, and this discharge consists of intermittent trains of electric oscillations with a periodic time equal to the free natural period of the oscillatory circuit. These discharges are made to succeed each other from 50 to 600 times a second by using an induction coil with an appropriate interrupter, or else an alternator and a transformer. If the arc method of exciting the oscillations is employed, then the ratio of capacity to inductance must be much smaller, and the oscillations are excited in this circuit by a continuous current arc worked with a voltage from 200 to 400 volts or more, the arc being traversed by a strong magnetic field, and generally being placed in a chamber kept free from oxygen. The oscillations set up in the condenser circuit are then persistent or unbroken. The oscillations are excited in the antenna by coupling it inductively or directly with the condenser circuit (Fig. 4). If the former method is employed, then an oscillation transformer is used consisting of two coils of wire, one coil being inserted in the condenser circuit and one in the antenna circuit, and according as these coils are near or far apart they are said to be closely or loosely coupled. These two circuits have, then, each their own natural period of electric vibration, like tuning-forks, and they have to be adjusted to syntony. It is well known that under these conditions oscillations set up in one circuit immediately create oscillations of two frequencies in both circuits. This action can be easily illustrated by two pendulums, which are of the same length and are hung side by side on a loose string distinguished by red and blue bobs. If one pendulum is set swinging it imparts little jerks to the other and sets the latter in motion, but to do this the first must part with its own energy, and hence is gradually brought to rest. Then the operation is repeated in the reverse direction. The motion of each pendulum may then be represented by the ordinates of a curve such as those in Fig. 5. This kind of motion can,

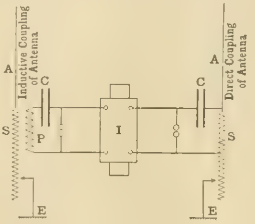

FIG. 4.

Red Pendulum

Blue Pendulum

FIG 5.

by a well-known theorem, be resolved into the sum of two oscillations of different frequencies. Hence each pendulum may be said to possess two rates of vibration. The same thing happens in the case of two closely coupled syntonic electric currents. If one circuit has free oscillations set up in it, the action and reaction of the circuits generates oscillations of two frequencies. Accordingly, when an antenna circuit is coupled to a condenser circuit we have oscillations of two frequencies set up in it, and waves of two wave-lengths radiated from the antenna. The presence of these two waves can be detected either by measurements made with the cymometer or by an oscillograph vacuum tube. In the first case, all that is necessary is to place a cymometer in proximity to the antenna and vary its oscillation constant. It will be found that there are two settings of the handle for which the neon tube glows brightly, and the scale of the instrument will indicate the wave-lengths of the two waves respectively.

Some instructive measurements of this kind have been made by Prof. W. G. Pierce in a recent research, and he has shown that the wave-length given by the formulæ which can be deduced from the theory of the operations are in agreement with actual measurements (Fig. 6). Another striking confirmation can be obtained by the oscillograph vacuum tube, invented by Dr. Gehrcke, of the Reichsanstalt, Berlin. This consists of a glass tube having two strip electrodes in it nearly touching, which are made of nickel or aluminium. The tube is filled with pure nitrogen and exhausted to a pressure of about 10 to 20 mm. If such a tube has a high voltage applied to its terminals a glow light extends along the electrodes, the length of which varies with the electromotive force. Hence, if the tube is connected to a circuit in which an oscillatory discharge is taking place, the glow light along the tube will rapidly extend and contract. If the electrodes are examined in a revolving mirror, making from fifty to a hundred turns a second, the images of the glowing electrodes corresponding to each oscillation will be separated out, and if the oscillations are persistent or undamped we see a series of short bright lines alternately above and below a central line. If, however, the oscillations are damped, then we see in the mirror a train of images each decreasing in length (Fig. 7). On applying such an oscillograph vacuum tube to the circuit of an inductively coupled antenna, and examining in a revolving mirror the image of the electrodes, they will be seen to present an appearance as in Fig. 8, taken from photographs kindly given me by Herr Hans Boas, of Berlin. These oscillograms indicate that there are two oscillations present of different frequency, producing an effect similar to beats in music. Owing to the difference in frequency, the oscillations alternately reinforce and extinguish each other throughout the period, and as this type of oscillogram is only obtained with an inductively coupled antenna, it is a proof that in such a case there are two oscillations present of different frequencies. A similar result has been obtained by Prof. E. Taylor-Jones with low-frequency oscillations in coupled inductive circuits by means of an electrostatic oscillogram of his own invention. Looking at these photographs, it will be seen that each represents a single train of damped oscillations gradually dying away, but that in each train of oscillations there is an alternate waxing and waning of the amplitude, which indicates that it may be considered to be composed of two superimposed oscillations of different frequency (Fig. 9).

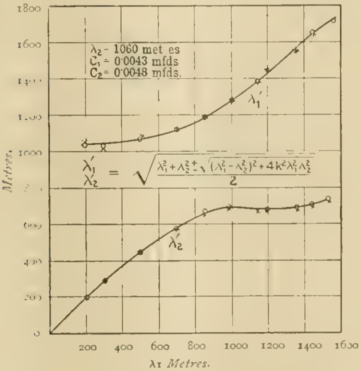

FIG. 6.—Pierce's Experiments on Inductive Coupling.

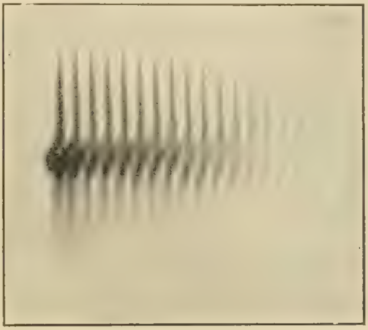

FIG. 7.—Oscillogram of Damped Oscillation (Antenna not connected) taken with the Gehrcke Oscillograph Vacuum Tube.

Accordingly, in the case of wireless telegraph antennæ inductively coupled, we have in general two waves radiated of different lengths, and either of these can be made to affect suitably tuned receiving circuits. These waves have different damping and different maximum amplitudes.

One of the disadvantages of close inductive coupling is, therefore, that we must divide the energy given to the antenna between two waves of different length. As the receiving antenna is generally only tuned to one of these wave-lengths, we then capture and absorb only the energy conveyed by the waves of that wave-length. To meet this difficulty it has been the custom to employ a feeble coupling between the circuits of the oscillation transformer, so as to generate waves of only one wave-length. The objection then arises that the energy conveyed to the antenna is

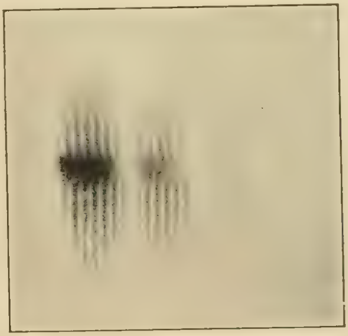

FIG. 8.—Oscillogram of Secondary Oscillation (Antenna connected) taken with Gehrcke Vacuum Tube.

much reduced. It is, however, possible, as I have shown, to duplicate the receiving circuits so as to capture the energy of both the waves even with close coupling of the transmitter transformer[1] (Fig. 10).

A method of creating feebly damped oscillations has, on the other hand, recently been developed, generally known in Germany as Wien's method, or the method of quenched sparks, which is based on the fact that if we can quench or stop the spark in the condenser circuit after the first few oscillations, the oscillations of the antenna then take place freely and with a single frequency (Fig. 11).

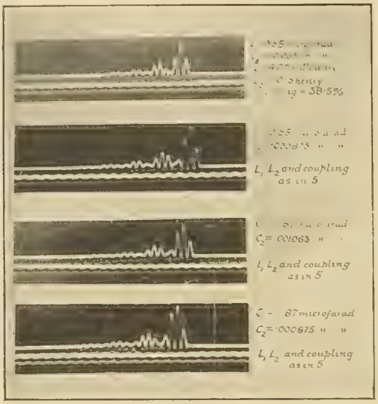

FIG. 9.—Oscillograms of Oscillations in Coupled Circuits by Prof. E. Taylor-Jones.

The principle which underlies this method is the well-known fact, to which particular attention was directed by Prof. M. Wien, of Danzig, in 1906, that the damping effect of very short sparks is extremely large. Hence if we form a spark-gap consisting of a large number of very small spark gaps in series, say ten gaps each of 0·3 mm., and if we keep the spark surfaces cool, then not only can no arc form between these surfaces, but the condenser spark is immediately quenched. Moreover, if we supply this spark-gap either from a high-frequency alternator or from a low-pressure transformer we can produce as many as 2000 sparks per second. A form of discharger for this purpose has been devised in Germany, which consists of a series of copper discs or copper boxes cooled with water, the flat surfaces of which are placed in contiguity, but separated by very thin rings of mica. The interspace between the boxes is not more than 1/125th part of an inch, and ten or twelve of these discs or boxes are placed in series (Fig. 12). The row of boxes takes the place of the ordinary spark balls, and is connected to the secondary terminals of a transformer, fed by a high-frequency alternator, and also connected to an oscillatory circuit. When the transformer is in action it produces a very large number, 1000 or more, oscillatory discharges of the condenser per second, each of which has a large initial amplitude, but quickly dies out. The inductively or directly coupled antenna hence receives a very large number of impulses per second, each of which sets up in it free electrical oscillations of one definite period.

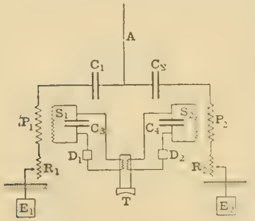

FIG. 10.—Method of utilising waves of both frequencies emitted by inductively-coupled Transmitting Antenna.

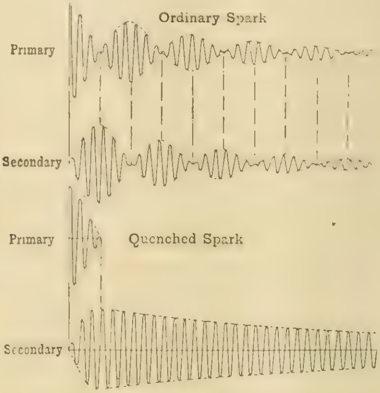

FIG. 11.—Oscillations in Inductively-coupled Circuits.

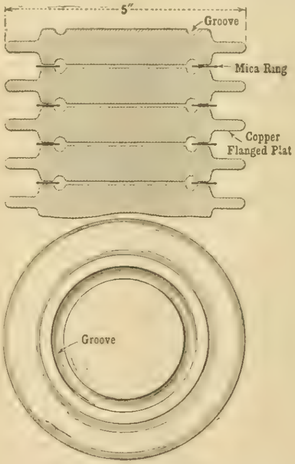
A discharger, composed of a single pair of metal plates with interposed separating paper ring, has been devised and employed by Von Lepel. In this case the plates are connected to the terminals of a high-voltage direct-current dynamo, and are shunted by a circuit having inductance and capacity, one of the plates being also connected to an antenna and the other to a balancing capacity.



Plan of Copper Flanged Plate.

FIG. 12.—Plan and Section showing portion of Discharger.

These discharges, however, have not stood the test of prolonged practical use, and we cannot say, therefore, that they are comparable in value for telegraphic purposes with the well-proved inventions of Mr. Marconi.

(To be continued.)

---

[1] Since the delivery of this lecture, my attention has been drawn by Mr. J. Hettinger to an article by himself in the *Electrical Engineer* of October 26, 1906, in which he describes an almost identical arrangement devised by him for capturing both the waves of an inductively-coupled transmitter, and refers to a prior invention for the same purpose by Dr. Seibt.

TWO REPORTS ON MARINE INVESTIGATIONS.[1]

THE staff responsible for scientific investigations and administration of fisheries under the Department of Agriculture and Technical Instruction for Ireland is attacking its problems with insight and energy, and is laying up a store of information of permanent value and interest. It is somewhat startling at this stage to note that Mr. Holt finds it necessary in his report on international investigations to expound the wherefore of hydrographical and plankton investigations and their bearing upon practical fishery problems. He states the case clearly and well, pointing out the necessity of studying the variations in the "annual ocean tide," of investigating the relation between salinity and plankton distribution, and of determining how far plankton conditions the abundance or absence of pelagic fishes, and hence may be taken as a guide in practical fishery pursuits. The ultimate end is the foretelling of physical conditions—favourable or unfavourable—from knowledge of prior causative factors, and thus preventing blindly tentative and unremunerative fishing operations. This research is of primary importance to Ireland, the staple fisheries of which are for the pelagic and plankton-eating mackerel and herring. The report further deals with the trawling survey of the deep-water grounds off the south-west coast, with mackerel and herring fisheries, oyster and other bivalve fisheries, and their artificial culture by the Department.

In connection with inland fisheries, a valuable fund of information is afforded by the publication of a summary of reports from many different local observers as to the migrations, abundance, and condition of salmon, grilse, and smolts. Local observations relating to the movements of eel fry up the Irish rivers are similarly collated.

Among the papers comprising the appendix is a second report on the Copepoda of the Irish Atlantic slope, by Mr. G. P. Farran, which deals with a total of 164 species, thirty of them being new and three being made types of new genera. The same naturalist writes on the distribution of the Thaliacea and Pyrosoma in Irish waters, discussing their occurrence in relation to hydrographical factors.

In collaboration with Mr. L. W. Byrne, the scientific adviser to the Department contributes a second report on the fishes of the Irish Atlantic slope, containing detailed descriptions and figures of Scorpænidæ and Alepocephalidæ, and a further list of recent additions to the British-Irish fish fauna. Two further appendices are the result of pioneer work under the auspices of the Ulster Fisheries and Biological Association: one by Mr. Geo. C. Gough on the bottom deposits of Larne Lough, and the other by Mr. H. J. Buchanan-Wollaston on the simple ascidians of the Larne district.

The volume on marine investigations in South Africa is a continuation of the reports on South African marine biology published by the Cape Department of Agriculture under the editorship of Dr. J. D. F. Gilchrist, Government biologist of the colony. Various groups of marine animals containing several new species of great interest form the subject of eight papers written by authorities, and well illustrated with thirty-five plates. Dr. Gilchrist's paper on new South African fishes adds to our knowledge of the deep-water forms two genera of Zeidæ and a new species of a genus already described for these waters, viz. Cyttosoma, which may be the adult of Cuvier and Valencienne's Oreosoma. A third new genus and five new species from the same locality are also described. Among notes on other deep-sea forms, perhaps the most interesting observations are in reference to sexual dimorphism in *Scopelus coccoi*, the males of which bear luminous scales on the upper side of the caudal region and the females on the lower side of it. Of shallow-water forms new species are described in the families of Scorpænidæ, Mugilidæ, Pleuronectidæ, and Clupeidæ. The Pelecypoda are dealt with by Mr. G. B. Sowerby, who describes thirty-three species new to science. A continuation of the report on Crustacea, by the Rev. Thos. R. R. Stebbing, contains accounts of further species—some showing remarkable characters as regards pigmentation and luminous organs—of Macrura, Brachyura, Schizopoda, and the interesting parasitic copepod *Penella orthagorisci*. Mr. P. T. Cleve adds to his plankton contributions a report on the Halocypridæ, Cypridinæ, and pelagic Annelida and Chætognatha. A new Cephalodiscus is described in minute detail by Dr. W. G. Ridewood, who includes in his paper a key to the identification of the seven species of this genus now known. A short paper by Prof. F. Jeffrey Bell describing three new crinoids is marred by three different renderings of the specific name of a new Antedon (presumably *A. magnicirra*). Still a fourth variation of spelling appears in the index!

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The syndicate appointed to consider the steps to be taken for the erection of a building for the Department of Agriculture reports that the erection of the building is now practically completed, and the fittings sanctioned are in a forward state. The syndicate anticipates that the building will be ready for occupation by the department at the beginning of the Lent term of 1910.

At a Congregation to be held on Thursday, December 9, at 2 p.m., it is proposed to confer the degree of Doctor of Science, *honoris causa*, upon Mark Aurel Stein.

A short address will be given at the Cavendish Laboratory on Monday, December 6, at 5 p.m., by Mr. G. F. C. Searle, on a course of experimental lectures on geometrical optics specially designed for candidates for the mathematical tripos, which has been arranged for the Lent term, 1910. A number of experiments, with very simple apparatus, illustrating the principles of geometrical optics will be shown. The attendance of mathematical teachers and others interested in the subject is invited.

MR. B. N. WALE, senior lecturer in agriculture at the South-eastern Agricultural College, Wye, has been appointed principal of the Seale-Hayne Agricultural College in Devonshire.

THE London University College Committee will shortly proceed to appoint a Derby scholar in zoology. The value of the scholarship is 60*l.* per annum, tenable for two years. Candidates must have been students of University College in zoology. Full particulars can be obtained from the secretary.

THE Lord Mayor has arranged a conference at the Mansion House on December 3, at 3 p.m., for the discussion of the question of industrial training in education, the development of trade schools, the position of apprenticeship and of the apprenticeship charities, and the establishment of employment bureaux to bring children leaving school into touch with employers of labour. The chairman and members of the London County Council are expected to be present.

A SUMMARY of the returns made to the Education Committee of the London County Council of attendances for the four weeks ended October 30 last at the polytechnics, technical institutes, and schools of art aided by the Council gives some striking results. The returns deal with ten polytechnics and twenty other institutions. In the polytechnics by October 30 last 20,820 individual students were enrolled since the beginning of the session, as compared with 26,410 in attendance for February last. The average number of student attendances a week was, for October, 61,158, and for February, 51,919. In the technical institutes and schools of art together, the grand total of individual students enrolled since the beginning of the session was, for October, 28,558, and for February, 35,911; the average number of student attendances a week were 73,482 and 62,357 respectively. It would appear from these numbers that the interest and enthusiasm of the students flag as the session advances, or else that the counter attractions of the winter prove too strong for a number of students.

THE October number of the Journal of the Association of Teachers in Technical Institutions contains the report of the council of the association for the year 1908–9. From this report we note that the association has applied to the Royal Commission on University and Higher Education in London to be allowed to lay its views on the subject before the commission, in the belief that the work of the commission will deal to a considerable extent with the polytechnics and technical schools of London. We also gather from an editorial note that the association, while anxious to secure coordination of the work of the polytechnics, looks on the scheme which has been put forward by the Education Committee of the London County Council as a curtailment of the powers of these institutions to do work of a university character, and is therefore opposed to the scheme. The association has also drawn up a scale of salaries for teachers in technical institutions in order to counteract the present tendency towards lower salaries. They propose that salaries of assistants begin at 150*l.* and go to 250*l.*, or 350*l.* for chief assistants in London polytechnics, and that heads of departments in the larger institutions have salaries from 350*l.* to 500*l.* per annum.

AT the meeting on November 24 of the Education Committee of the London County Council an important application from the Imperial College of Science and Technology was considered. The governing body desires the Council to make a grant of 8000*l.* to the college in respect of the financial year ending August 31, 1910, as compared with a grant of 5000*l.* for the previous financial year. Application was also made for a special grant of 350*l.* in respect of the teaching of aëronautics. The committee decided that, without in any way committing the Council to the payment of an annual grant, and subject to twenty-five free places being reserved for the Council's scholars, 8000*l.* should be allowed to the governing body of the Imperial College for the year named, that 5000*l.* of the amount should be paid during the current financial year, and the remaining 3000*l.* between April 1 and July 31 next. It was further agreed that the Council, in considering any future application for grant, should ask to be informed what steps had been taken by the governing body "to prevent overlapping and secure coordination of the work already carried on by university colleges, polytechnics, and other science and technological institutions, and the proper connection of the whole with the university," and also what further provision for maintenance is to be obtained from funds of a national character. The special grant for the teaching of aëronautics will not be made.

WE have received a copy of the annual report on the 113th session's work of the Glasgow and West of Scotland Technical College, adopted by the governors of the college at their meeting last September. The record of the year shows continued development in the work of the college; full advantage has been taken of the new departures enumerated in the report of last year, and these have had a satisfactory influence upon the standard as well as upon the volume of the work of the session. An important modification has been made in the general curriculum for the diploma awarded by the college, having especial reference to the examination tests to which candidates have been subjected hitherto. It has been the practice in the college to hold special sessional examinations in which it was necessary that a candidate for the diploma should show the attainment of a certain standard of proficiency. Although the examiners were in the habit of taking some note of the class-work before coming to a decision on the merits of a candidate, it was inevitable that the greatest weight should be attached to the results of these special examinations. The departure referred to consists in a reorganisation of the work for the diploma which will permit of the special being combined with the class examinations, and of a student's position each session being determined by the examiners after a review of his whole work for that, and, if need be, for the previous sessions. This review will take account of examinations, drawings, practical work as shown by laboratory books, and other classwork. Part of the work for the final year will be the preparation of a design, the composition of a thesis, or the like, done, not under examination conditions, but as nearly as possible under those which obtain in everyday professional life. It is interesting in this connection to note that Prof. Perry, F.R.S., who was appointed by the Scotch Education Department to make the special inspection of the college for this session, does not think it possible "for the college to take its proper position until it can confer the B.Sc. degree upon all its students who pass satisfactorily through courses of study which satisfy its own council of professors." His report has been brought before the notice of the Court of the University of Glasgow, and of a committee appointed by them to consider the question of future relations with the Glasgow and West of Scotland College.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, November 12.—Dr. C. Chree, F.R.S., president, in the chair.—P. V. **Bevan**: The absorption spectrum of potassium vapour. The method of studying the absorption spectrum was that used first by Roscoe and Schuster, and of late years elaborated by Prof. R. W. Wood. That the optically dense vapour has small density makes it possible to heat the metal in a tube, and to have enough vapour to show strong absorption of light with little distillation to the colder parts of the tube. A tube with quartz plate ends can be used, and the absorption spectrum studied with a quartz spectrograph. The most evident feature of the spectrum obtained is the appearance of the lines of the principal series. None of the lines of the two associated series appear, but additional channelled space spectra unrepresented in the emission spectra. Fifteen new lines have been obtained in the principal series by this method. In the invisible region there appears a channelled space spectrum in the red. This shows definite edges of bands towards the violet end of the spectrum. The wave-lengths of the edges of these bands were measured. When the ratios of these wave-lengths to that of the first member of the principal series are found, the values are found to be in the same range as the corresponding ratios as deduced from Wood's measurements on sodium absorption. This the author regards as evidence of connection between the channelled space spectrum and the principal series of lines. The remarkable feature of this absorption spectrum is the difference in the properties of the principal series lines from those of other lines in the emission spectrum. Some other lines are in emission spectra far stronger than the higher members of the principal series, yet do not appear at all in the absorption spectrum. This fact may indicate that the metallic vapour at the low temperature of these experiments is in a different molecular state from its state in a spark or flame, or that in these latter cases chemical action is going on and the emission spectrum is not a simple elementary spectrum.—J. S. **Dow**: Some further notes on the physiological principles underlying the flicker photometer. The author suggests that something may be learned regarding the physiological phenomena governing the flicker photometer by observing whether it is subject to certain physiological effects, such as the "yellow spot" and "Purkinje" phenomena. Experiments show that the effects referred to do occur, but are apparently much less marked. The author suggests an explanation based on the assumption that the rod-elements on the retina, in addition to the peculiarities attributed to these organs as regards the perception of light and colour, also differ from the "cones" in the fact that they seem to receive a luminous impression more slowly, and retain it longer than these organs. This peculiarity is of little consequence in an ordinary photometer of the equality of brightness type, but may play a part in the flicker instrument; it seems to explain why certain effects should be perceived more clearly in one case than in the other. According to this theory, we may imagine the flicker effect to be due to two distinct portions, received by the agency of the rods and cones respectively. Under certain conditions the speed of a flicker photometer may be supposed to be suitable for the use of "cone-flicker" but too high for the "rod-flicker," which becomes fused into a steady luminous impression, and thus does not affect the readings of the instrument. The author regards his experiments as being essentially of a suggestive character, requiring more detailed examination. One must be cautious in seeking to draw deductions from cases of colour-blindness, as many different varieties of this affliction exist.—Dr. Edridge **Green**: Colour-perception spectrometer. This consists of an ordinary spectrometer with a single prism, fitted with two wave-length drums, which work two shutters placed in the focal plane of the eyepiece. By means of the shutters any part of the spectrum can be viewed at will, and the wave-lengths of the edges of the patch under observation can be read off from the drums. Dr. Green described how the instrument is used for testing colour-blindness, and referred to the superiority of the method over those usually adopted.—H. G. **Savidge**: Tables of the ber and bei and ker and kei functions, with further formulæ for their computation.

Mineralogical Society, November 16.—Prof. W. J. Lewis, F.R.S., president, in the chair.—J. B. **Scrivenor**: An occurrence of native copper with tin ore in the Federated Malay States. In concentrates obtained in the final washing of the tin ore from the Rotan Dahan mine in the district of Kinta, Perak, the cassiterite was found to be mixed with a reddish mineral, which could not be separated from it. This proved to be native copper in minute and beautifully sharp crystals. The tin ore is obtained from a mass of partially decomposed soft schists overlying limestone, and the copper was probably the result of reduction *in situ* of a copper salt held in solution by water percolating through the schists.—Dr. G. T. **Prior**: A meteoric stone from Simondium, Cape Colony. Two or three masses of a meteoric stone were discovered in 1907, 100 yards apart and a foot below the surface, in gravel near Simondium Station, on the Paarl to French Hoek line, in Cape Colony. The masses, of which the largest was not more than a foot in diameter, were broken up by the finders, who supposed the particles of nickel-iron seen on the fractured surfaces to be native silver. Six of these fragments, which were preserved, have been presented to the British Museum collection by Mr. R. T. Hancock and Mr. R. H. Stanley, one of the prospectors who discovered the masses. The meteorite belongs to the less common class of aërolites which show no chondritic structure; it consists of enstatite, olivine, and felspar, with nickel-iron, magnetite, and some troilite.—L. J. **Spencer**: The occurrence of alstonite and ullmannite (a species new to Britain) in a barytes-witherite vein in the New Brancepeth Colliery, near Durham. A large vein of barytes, coinciding with a fault, in the New Brancepeth Colliery is worked commercially on a large scale for barytes, and has yielded many finely crystallised mineral specimens. These include barytes and witherite in large crystals, and the rare species alstonite and ullmannite (NiSbS, with 28 per cent. of nickel), the latter of which has not been previously recorded in the British Isles. Galena, blende, copper-pyrites, iron-pyrites, and melanterite are also present in small amount. The order of formation of the non-metallic minerals is (1) barytes, (2) witherite, and (3) alstonite, the two last having been derived from the barytes. The ullmannite is found as cubes of considerable size and as octahedra, and it sometimes forms a parallel intergrowth with galena.—Prof. W. J. **Lewis**: Sartorite and other minerals from the Binnenthal. A crystal of sartorite showing twin lamellæ was described.

Royal Anthropological Institute, November 16.—Prof. W. Ridgeway, president, in the chair.—F. G. **Parsons**: The Rothwell crania. The church of Rothwell is situated in the north of Northamptonshire. About 200 years ago some workmen discovered the existence of a crypt, in which was stored a large number of human skulls and other remains. The date *circa* 1700 is the latest, therefore, to which the skulls can be assigned. As, however, at the time of their discovery all knowledge of their existence had been lost, it is safe to consider 1600 as the latest possible date for them. On the other hand, they can hardly be earlier than 1180, which is the earliest date to which can be assigned the vault in which they are stored. There are probably some five or six thousand individuals represented in the vault, and it is practically certain that, as at Hythe, the bones represent the burials of a very considerable number of years, removed at various times to the vault when the graveyard became overcrowded. It seems justifiable, therefore, to consider the bones as being the remains of English men, women, and children, most of whom lived in the fourteenth and fifteenth centuries. It is interesting to notice that, except for a greater breadth of forehead, these Rothwell crania are almost identical with those of the students at St. Thomas's Hospital, measured by the author. On the whole, however, the Rothwell crania are slightly larger. The bones are in a very bad condition owing to the damp.

Royal Meteorological Society, November 17.—Mr. H. Mellish, president, in the chair.—C. J. P. **Cave**: Methods employed for observing pilot balloons used for investigating the currents of the upper atmosphere. Two theodolites are used, each at the end of a measured base-line, and observations of the balloon are taken each minute from its start. The readings are subsequently worked out and plotted graphically, when the height, direction, and rate of travel of the balloon during its course are determined. The best time for observing balloons is shortly before sunset, as the sky will be becoming dark when the balloon reaches its greatest height, and, being illuminated by direct sunlight, will shine like a star. The author has seen a balloon burst at a distance of forty miles under these conditions. The rate of ascent of balloons is found to vary considerably near the ground, and in cloudy weather, particularly when there is cumulus cloud, but higher up the rate of ascent remains fairly uniform up to great heights.—W. **Marriott**: Registering balloon ascents at Gloucester, June 23 and 24, 1909. During the Royal Agricultural Society's recent show the author sent up *ballons-sondes* with recording instruments on three consecutive days. Two of the meteorographs were found and returned. The balloon on June 23 fell thirty-seven miles south-east, and that on June 24 fell forty-three miles north of Gloucester. The records showed that the temperature decreased pretty uniformly up to between five and six miles; above that height the temperature increased somewhat, and then kept nearly stationary up to the highest point reached by the balloons, about twelve miles. The temperature recorded on June 23 was higher than that recorded on June 24, and the point of change, or the so-called "isothermal layer," was about half a mile lower in altitude. This was probably due to the balloon on June 23 having ascended on the eastern side of the centre of a cyclone, while that on June 24 ascended on the western side of the centre.—W. P. **Brown**: Winter temperatures on mountain heights. In 1867 the author placed a minimum thermometer on the summit of Y Glyder-fach, a mountain near Snowdon, and 3262 feet above sea-level, and this has been regularly observed and the lowest winter readings recorded each year. The author gives the readings in full.—E. **Gold**: The semi-diurnal variation of rainfall. The results of the author's investigation seem to indicate that the upward motion associated with the semi-diurnal variation of pressure is the probable cause of the semi-diurnal variation of rainfall.

Geological Society, November 17.—Prof. W. J. Sollas, F.R.S., president, in the chair.—A. R. **Andrew** and T. E. G. **Bailey**: The geology of Nyasaland. E. A. N. **Arber**: Description of the fossil flora. R. B. **Newton**: Notes on the non-marine fossil Mollusca. Dr. R. H. **Traquair,** F.R.S.: Description of the fish-scales of Colobodus, &c. The greater part of Nyasaland consists of crystalline rocks, which comprise:—(*a*) metamorphosed sedimentary beds, including graphitic gneisses with limestones, and muscovite-schists; (*b*) foliated igneous rocks, especially augen-gneiss; (*c*) plutonic intrusions, usually granite or syenite, more rarely gabbro. In the N.W. corner of Nyasaland is an altered sedimentary series, which forms the Mafingi Hills. It consists of accumulations of quartzites, grits, and sandstones of pre-Karoo age. The Karoo system is represented both in the north and in the south of Nyasaland; in the north it occurs in patches. It has afforded remains of fresh-water lamellibranchs (Palæomutela), fish-scales (Colobodus), and species of Glossopteris. Recent lacustrine marls and sands are found at great heights above the present level of the lake, and as much as fifteen miles away from its margin. Pumiceous tuffs are found in the north of the country; across the border, in German East Africa, Tertiary and recent lavas and tuffs are distributed widely. Nyasaland consists of high plateaux rising irregularly one above the other.—S. **Smith**: The faunal succession of the Upper Bernician. The Bernician series forms the upper division of the Lower Carboniferous sequence of Northumberland. Below the Bernician lie the Tuedian beds. The Northumberland succession, together with the Lower Carboniferous rocks north of the Tweed, occupies the northern extremity of the Pennine province of the Carboniferous Limestone series. The Carboniferous strata in Northumberland encircle the Cheviots on the south, east, and north, and dip from the volcanic inlier. The Bernician is mainly built up of sandstones and shales, but intercalated are beds of limestone and numerous seams of coal. In the Upper Bernician the limestones are fairly thick, constant, and truly marine. The calcareous beds of Lower Bernician age are thin, impure, and frequently contain Stigmaria. There are a few good marine limestones of local occurrence. The Upper Bernician answers to Tate's calcareous group, while the Lower Bernician is equivalent to Tate's carbonaceous group. It is with the Upper Bernician only that the present paper is concerned. The whole of the Upper Bernician Limestones belong to the Dibunophyllum zone, but they are capable of palæontological subdivision, as is given in the paper.—M. K. **Heslop** and Dr. J. A. **Smythe**: Notes on the dyke at Crookdene (Northumberland), and its relations to the Collywell, Morpeth, and Tynemouth dykes. The dyke at Crookdene is exposed in the bed and banks of the Wansbeck above Morpeth. It is intruded along a fault-fissure in beds of Bernician age. The basalt contains narrow lath-shaped felspars and curved augites. Large inclusions of a felspar, closely allied to anorthite, occur. The exterior of the inclusions in contact with the ground-mass is zoned; the individual crystals are intergrown, cracked, faulted, and in places shattered. These phenomena point to a plutonic origin of the felspathic inclusions, and connect them with the porphyritic felspars of the Tynemouth Dyke, for which a similar origin has been suggested by Dr. Teall. The dyke, which comes to a head in the coast-section at Collywell, shows the same peculiarities. The two basalts are practically identical. It appears probable that they belong to the same intrusion. The work of Dr. Teall has been amplified by further observations. The resemblances among the four dykes are so strong as to render it probable that they are derived from a common source.

Royal Microscopical Society, November 17.—Mr. F. J. Cheshire, vice-president, in the chair.—E. **Heron-Allen** and A. **Earland**: The recent and fossil Foraminifera of the shore-sands of Selsey Bill, Sussex, part iv. This paper covered the genera Cycloloculina to Nummulites inclusive, and included many rare and interesting forms, but no new species. Of the genus Cycloloculina, first described by the authors in 1908 from this locality, a few additional details were mentioned, but the original source of the specimens still remains doubtful, although its distribution has now been worked out over an extensive area of the peninsula. The evidence, however, points to the Eocene beds of Bracklesham Bay as the source from which the specimens were derived, although none have been found *in situ*. The paper was illustrated by a series of lantern-slides, photographed from specimens specially mounted for the purpose.

Linnean Society, November 18.—Dr. D. H. Scott, F.R.S., in the chair.—W. **Wesché**: A new Tipulid subfamily. The flies which form this well-marked subfamily were brought to the author's notice by Lieut.-Colonel Winne Sampson, who collected them in S. Nigeria. The striking proboscis, more like the mouth-parts of the Culicidæ than of the Tipulidæ, marks them off from all other genera of the latter family, except Geranomyia; but though Geranomyia has greatly developed mouth-parts, they are quite different in type, the paraglossæ being cleft, and the palpi, though single-jointed, being situated at the base of the labium instead of at the tip, as is the case in the Ceratochilinæ. Colonel Winne Sampson's specimens were all mounted as preparations for the microscope, but the author found five pinned, unnamed insects in the British Museum which had been collected by Dr. Graham in Ashanti, and which agreed with the Nigerian species as regards the trophi and peculiar antennæ, but presented generic differences in the wing venation. This genus he has called Neoceratochilus, as the venation is less archaic in type than that of the other genus, which the author names Ceratochilus, or horned or palped lip.—J. M. **Brown**: Fresh-water rhizopods from the Lake District. The author stated that between forty and fifty species had been obtained from Sphagnum and sediment from tarns and lakes, amongst them some which had not been previously recorded as occurring in Britain, with one species new to science. After enumerating the forms found at certain localities, the author gives some critical remarks on some of the species obtained.

Zoological Society, November 23.—Dr. A. Smith Woodward, F.R.S., vice-president, in the chair.—G. C. **Shortridge**: An account of the geographical distribution of the Marsupials and Monotremes of South-west Australia, having special reference to the specimens collected during the Balston Expedition of 1904–7.—Mrs. E. W. **Sexton**: Notes on some Amphipoda from the north side of the Bay of Biscay. The paper contained notes on the development of the females of certain Amphipoda, showing that structural modification continues even after sexual maturity is reached, and this may give rise to differences of so striking a character that earlier and later stages might easily be mistaken for distinct species. This was illustrated by examples from the families Pleustidæ and Eusiridæ.—Lieut.-Colonel J. M. **Fawcett**: Aberrations in Nymphalinæ from the Andaman Islands, and of *Papilio clytia* from Burma.—R. **Lydekker**: Note on the cetacean *Sotalia borneënsis*. A correction of the author's description of this species published in the society's Proceedings for 1901 (p. 88, pl. viii.).

DUBLIN.

Royal Dublin Society, November 23.—Prof. H. H. Dixon, F.R.S., in the chair.—J. **Adams** and Prof. T. **Johnson**: Bacterial rot in the turnip and other brassicas. Three different bacterial diseases are referred to:—(1) brown rot of turnips caused by *Pseudomonas campestris*, Smith; (2) white rot of turnips caused by *Pseudomonas destructans*, Potter; (3) black rot of cabbages caused by *Bacillus oleraceae*, Harrison. The characters of each are described, and an outline of their distribution in Ireland is given. A comparison of the characters of the organisms responsible for numbers (2) and (3) is given in parallel columns, and the inference is drawn that they are the same species. Further confirmation of this conclusion is afforded by infection experiments.—Prof. Henry H. **Dixon** and W. R. G. **Atkins**: Osmotic pressure in plants and on a thermo-electric method of determining freezing points. In this paper the authors describe a thermo-electric method of cryoscopy, and arrangements by which the freezing point of small quantities of liquids (about 2·5 c.c.) may be determined with considerable accuracy to 0·01° C. The method was devised for determining the freezing points of the cell-sap of plants, and by that means to obtain the value of the osmotic pressure in the tissues. More than a hundred determinations were made, and these showed pressures in the leaves of plants ranging from 3·7 to 27 atmospheres. So far as the observations have gone, assimilation appears to be the most important external factor controlling the osmotic pressure of the leaves, which may vary widely in the same plant. Exposure to conditions favouring the fixation of carbon may cause the upper leaves to have a higher osmotic pressure than the lower, or *vice versa*. The determinations of the osmotic pressure are in most cases accompanied with determinations of the mean molecular weight of the substances giving rise to the pressure, so that some idea of the nature of these substances may be formed. The roots examined showed a lower osmotic pressure than the leaves.—Dr. J. R. **Sutton**: Some observations of dew at Kimberley (South Africa). This paper gives the results of some routine observations of dew. The author concludes that, contrary to the usual statements of the text-books, a clear sky is by no means essential to the formation of dew. A clear sky will, as a rule, hasten the beginning of the condensation of moisture from the air, but in the long run as much dew may be deposited when there are clouds as when there are none. When the air is very near the saturation point, the radiation of heat from the earth's surface is not much more intense under a clear sky than it is under clouds. Dew-making is not so much a function of the clearness of the sky as of the dampness of the air and the length of the night.

Edinburgh.

Royal Society, November 22.—Sir William Turner, K.C.B., president, in the chair.—Prof. Alex. **Smith** and Prof. A. W. C. **Menzies**: A new hydrate of orthophosphoric acid. The new hydrate has the composition $10H_3PO_4,H_2O$. It was obtained in quantity by concentrating orthophosphoric acid to 96 per cent., and keeping it at 24·38°. Mechanical stirring for a few hours brought about crystallisation, the crystals being large transparent prisms similar to those of Joly's hydrate.—Dr. J. A. **Gunn**: The pharmacological action of harmaline. Harmaline is one of two alkaloids found in the seeds of *Peganum harmala*. These seeds have been used medicinally, especially in India, for a variety of purposes, but the nature of their pharmacological action has not been thoroughly investigated. The present investigation shows that harmaline belongs to the group of general protoplasmic poisons, and resembles quinine in its pharmacological actions.—Dr. D. Berry **Hart**: Mendelism and zygotic segregation in the production of anomalous sex, i., the Free-Martin. John Hunter first described the anomalous sterile twin, known as the Free-Martin, found chiefly in black cattle. The Free-Martin is a sterile animal like a heifer, the co-twin of which is a potent bull. John Hunter described three specimens, and, on naked-eye examination, stated that the sexual gland was an ovary in one, a testis in a second, and that in the third both ovary and testis were present. Spiegelberg, of Breslau, examined a Free-Martin calf the co-twin of which was a bull, and described the organs in detail, concluding that the Free-Martin was a sterile bull with very rudimentary Müllerian relics. Numan, of Utrecht, published a memoir on sterile cattle, and figured several specimens comparable with John Hunter's. Although in error in some of his conclusions, he established a most important fact, which Dr. Berry Hart had anticipated theoretically, viz. that there may be a Free-Martin with rudimentary external male genitals the co-twin of which is a potent female. This Free-Martin (Stier-Kween of the Dutch) is thus a sterile female. The conclusion arrived at in the paper was that the Free-Martin and its twin were derived from a single zygote, the potent organs being segregated in the potent twin, the non-potent in the sterile animal. Thus a male zygote gave rise to a potent bull and a sterile bull, the ordinary Free-Martin, while a female zygote gave a potent female and a sterile female. The potent and non-potent elements in each sex behave usually as a complete unit, but in black cattle they segregate in twinning. This explains the puzzling anomaly. The potent and sterile twins may thus be described as an extracted dominant and an extracted recessive respectively, and placed in F^2 of the ordinary Mendelian scheme.—Dr. Thomas **Muir**, F.R.S.: The theory of orthogonants in the historical order of development up to 1860.

Paris.

Academy of Sciences, November 22.—M. Bouchard in the chair.—G. **Darboux**: Congruences of curves.—Yves **Delage**: The true causes of the supposed electrical parthenogenesis. A repetition, under more stringent conditions, of the experiments described in an earlier paper has shown that the conclusions given were not well founded. Electric charges, as such, do not produce parthenogenesis. Electrolysis produces a slight effect, solely on account of the formation of acid and alkali at the electrodes.—A. **Lacroix**: The existence of rhodizite in Madagascar pegmatites. This mineral is a boroaluminate of beryllium, lithium, sodium, and potassium, of the composition

$$6B_2O_3.4Al_2O_3.4BeO,4(Li,K,Na,H)_2O.$$

—Lecoq **de Boisbaudran**: The band spectra of barium and aluminium.—M. Simon was elected correspondant for the section of anatomy and zoology, in the place of the late M. Bergh.—M. **Borrelly**: Observations of Halley's comet made at the Observatory of Marseilles with the comet finder. The positions of the comet and comparison stars are given for November 19 and 20.—J. **Haag**: Certain groups of families of Lamé.—S. **Carrus**: The integration of partial differential equations.—Marcel **Riesz**: Dirichlet's series and integral series.—B. **Szilard**: An apparatus for radio-active measurements. An instrument based on the principle of the electroscope, but in which the gold leaf is replaced by a rigid index, a magnetised steel needle.—Georges **Claude**: The desiccation of air before liquefaction. A small quantity of alcohol, nearly equal to the weight of water vapour in the air, is added to the air on its way to the compressor; this does not solidify, and can be readily separated in liquid form in the course of the cooling process.—A. **Dufour**: Asymmetry of certain emission bands of vapours in the Zeeman phenomenon.—E. **Caudrelier**: The function of the capacity of the electrodes in the discharge of inductors.—MM. **de Broglie** and **Brizard**: Chemical reactions and ionisation of gases. A criticism of work of M. Reboul on the same subject.—Jean **Meunier**: The conditions necessary for platinum to remain in a state of incandescence in a Bunsen burner. Experiments are detailed tending to show that the property of remaining incandescent in an air-gas mixture is not due to the platinum alone, but to minute traces of saline substances of the order of 0·001 milligram carried by the wire.—H. **Dautriche**: The working of safety explosives containing ammonium nitrate in presence of coal, paper, and paraffin. Coal-dust surrounding the cartridge is burnt to carbon monoxide during the explosion.—A. **Guyot** and A. **Gry**: Some new syntheses of vanillin. Mesoxalic ether and an αβ-diketonic ester are condensed by chloride of zinc in glacial acetic acid, and the product converted into a vanilloyl-carboxylic acid by heating with an aqueous solution of copper acetate.—Marcel **Guerbet**: Some condensation products of camphor.—Henri **Lecomte**: Floral pedicels.—M. **Marage**: Studies of laryngeal vibrations.—J. **Comandon**: The kinematography of living micro-organisms and mobile particles with the aid of the ultra-microscope.—M. **Baudran**: A tuberculous endotoxine of albumose nature. The separation of the albumose from the bacilli is described in detail; it proved to exert toxic effects on guinea-pigs.—L. **Bull**: Researches on the flight of insects.—C. **Gerber**: The ferment of the Basidiomycetes.—A. **Goris** and M. **Mascré**: The existence in *Primula officinalis* of two new glucosides hydrolysable by a ferment. The glucosides are named primeverine and primulaverine; both are unacted upon by emulsin, but are hydrolysed by boiling dilute sulphuric acid.—E. L. **Trouessart**: A new insectivorous type (*Neotetracus sinensis*) from western China.—Jean **Boussac**: The Nummulitic of the eastern Alps.

New South Wales.

Royal Society, August 4.—Mr. H. Deane, vice-president, in the chair.—J. H. **Maiden** and R. H. **Cambage**: Botanical, topographical, and geological notes on some routes of Allan Cunningham.

September 1.—Dr. Walter Spencer, vice-president, in the chair.—T. H. **Johnston**: A new genus of bird-cestodes.—S. G. **Walton**: A complete analysis of Sydney water.—J. H. **Maiden**: A plea for the study of phenological phenomena in Australia.

Cape Town.

Royal Society of South Africa, October 20—Mr. S. S. Hough, F.R.S., president, in the chair.—Dr. M. **Wilson**: Nutmeg poisoning. The symptoms were described and attention directed to the small number of cases recorded. As the condiment was used practically throughout the whole world, the explanation must be that a few nutmegs had gone into circulation after germination had begun and then been arrested. In support of this the author directed attention to the fir seed (dana pitje), which was greatly relished and largely eaten by children near Cape Town without any bad results; but when one seed which had started to germinate was eaten, the results were very serious and dangerous.—Dr. R. **Broom**: Observations on some specimens of South African fossil reptiles preserved in the British Museum. The following are some of the conclusions come to by the author:—All the later specimens which have been referred to Galesaurus are held to belong to a different genus and species, and must take Owen's name *Nythosaurus larvatus*. Gorgonops is held to be closely allied to Titanosuchus, and to be really a dinocephalian. Theriognathus is believed to be very distinct from Endothiodon, and to be really a therocephalian. Anthodon is held to include at present two entirely distinct forms. The type is a small pareiasaurian from the Permian beds of Styl-Krantz. The teeth from the

Cretaceous bed of the Bushman's River, which have hitherto been placed under Anthodon, are held to be dinosaurian, and for them the new name *Palacoscincus africanus* is proposed.—L. **Péringuey** and E. J. **Phillips**: Notes on a zoological and botanical collections from the group of islands of Tristan d'Acunha, made by Mr. J. C. Keytel, 1908–1909. The botanical specimens came from Tristan only, while a few birds were obtained from Nightingale Island; the remainder, however, was collected at Tristan itself. Mr. Keytel collected seven of the twenty species endemic to the island, as well as sixteen plants that have been introduced within the last thirty years, as no mention is made of them by Moseley, of the *Challenger* expedition; among the birds was found a cuckoo, a native of South America, *Coccyzus melanocoryphus*. Among the insects, all but one are introductions, mainly from the Cape, but also from extreme South America. The Cape crawfish, *Jasus lalandei*, occurs also at Tristan, as well as several fishes found on the Cape Colony coast.—A. W. **Roberts**: Absorption of light by the atmosphere. The investigation was undertaken for the purpose of obtaining a value of the coefficient of absorption for South Africa. Taking the means of all the results, Dr. Roberts obtains as the value of the coefficient of atmospheric absorption $0^{m}20$, which, interpreted into other terms, means that 17 per cent. of all rays that strike the atmosphere perpendicularly are absorbed by the atmosphere.—L. **Péringuey**: The age of Stone (Palæolithic) in the Drakenstein Valley and the manner in which the implements were made. A large collection of implements of a huge size were exhibited. It was found possible from the material found in that valley to reconstruct the artificial working of those implements from the fractured, water-worn quartzite boulder to implements of a finish equal to the best Acheulean. The division of Chellean, Acheulean, Mousterian, cannot be adopted in South Africa, as the three typical forms were found together and in all stages of finish. The extreme antiquity of the implements shown was demonstrated by the well-nigh disintegrating sandstone of which they are made, as well as by the abraded edges of many of these palæoliths. In fact, some that had been long exposed seem to be preserved by the patina they acquired through the exposure.

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 2.

RÖNTGEN SOCIETY, at 8.15.—Some Effects of Electrical Discharges on Photographic Plates: Prof. A. W. Porter.

LINNEAN SOCIETY, at 8.—Nudibranchs from the Indian Ocean: Sir Chas. Eliot, K.C.M.G.—Trichoptera von Mr. Hugh Scott, auf den Seychellen gesammelt: Dr. Georg Ulmer.—Report on the Brachiopoda obtained from the Indian Ocean by the *Sealark* Expedition, 1905: Dr. W. H. Dall.—Narrative of the *Sealark* Expedition, Part III.: Prof. J. Stanley Gardiner, F.R.S., and others.

SOCIETY OF DYERS AND COLOURISTS, at 8.—The Testing of Tanning Materials from a Dyer's Standpoint: W. P. Dreaper.—Methods of Testing Dyes for Fastness: Dr. E. Feilmann.—Some Problems in Leather Dyeing: M. C. Lamb.—The Purchase and Testing of Dyestuffs: H. P. Pearson.

FRIDAY, DECEMBER 3.

PLANT RECORDS OF THE ROCKS.

Studies in Fossil Botany. By Dr. Dukinfield H. Scott, F.R.S. Second edition. Vol. I., Pteridophyta. Pp. xx+363. Price 6*s.* net. Vol. II., Spermophyta. Pp. xiii+(355–676). Price 5*s.* net. (London: A. and C. Black, vol. i., 1908; vol. ii., 1909.) Price, 2 vols., 10*s.* 6*d.* net.

IN the preface to the first edition the author expressed the hope that the palæontological record "will no longer be ignored by students of the evolution of plants." Since these words were written the study of the plant-records of the rocks has made steady progress, not only as regards results, but in the vigorous growth of interest shown in the relics of past floras. This remarkable activity is in large measure the direct result of the influence exerted by Dr. Scott, not only by his own researches and by the encouragement and generous assistance which he is always ready to give to younger workers, but in no small degree by his well-balanced and lucid treatment of that branch of botany to which he has devoted himself with conspicuous success.

The recent issue of the "Studies" is a new edition in more than name; two volumes replace the single volume in which the lectures were originally published, and, as the result of the rapid progress of palæobotanical work during the last eight years, many of the chapters have been largely re-written and others have been amplified. In the section devoted to the Equisetales the additions are few; reference is made to Mr. Hickling's recent account of the course of the vascular bundles in the sporangiophores of *Palaeostachya vera,* and to Halle's monograph of Mesozoic species of Equisetites. In the first edition a brief reference was made to the important discovery of Lepidocarpon, a seed-bearing lycopodiaceous strobilus: subsequent work by Dr. Scott and others has now rendered possible a more adequate treatment of this and similar types. A drawing of a transverse section of *Lepidodendron Wunschianum,* published in the first edition, is again reproduced with a broad band of tissue labelled "phloem," though it consists of extremely short parenchymatous cells, and a few immature xylem elements. It is a fact of considerable interest that in Lepidodendron stems which have formed a broad cylinder of secondary xylem, no true secondary phloem has been discovered. To the consideration of this question Dr. Scott hardly does justice. There are still many points to be cleared up in regard to the morphology of Palæozoic lycopods, and this can be done only by a detailed comparative treatment of all known species, founded on anatomical characters.

It is, however, especially in the account of the ferns that the results of recent investigations are most apparent. The student of Palæozoic ferns has now to face the difficulty of distinguishing between true members of the Filicineæ and fern-like plants which bore seeds. The account of the Botryopterideæ, a group of ferns which has gained considerably in importance since the removal of many genera of Palæozoic "ferns" to the new group Pteridospermeæ, is particularly welcome as coming from one who is exceptionally well qualified to deal with these still imperfectly known types. The excellent description, which is necessarily condensed, leads one to express the hope that Dr. Scott will soon publish a more comprehensive account of his researches into the structure and affinities of these generalised ferns. The account of the genus Lyginodendron has been modified as the result of Dr. Kidston's important contribution to our knowledge of the male reproductive organs, which had been previously referred to Zeiller's genus Crossotheca and regarded as fern sporangia. The chapter on the Medulloseæ contains interesting new matter, including some admirable drawings by Mr. Maslen of the seed Trigonocarpon and photomicrographs illustrating Prof. Oliver's recent work on the multicellular pollen-grains, and what are believed to be the remains of motile male gametes of Stephanospermum.

A word of praise is due to the publishers for the quality of the type and for the successful reproduction of the illustrations. Some new figures have been added, the most striking of which is, perhaps, a drawing of a transverse section of a young vascular bundle of *Botryopteris hirsuta,* showing the thin-walled immature xylem, with a few lignified protoxylem elements. It is no exaggeration to say that the volumes before us afford the most convincing demonstration so far presented in book-form of the possibilities of palæobotanical research. As we read the descriptions of many of the extinct types, and note the perfection of the preservation of their tissues, we forget that the material from which the data have been obtained has for countless ages been entombed in the older rocks of the earth's crust.

Though mainly concerned with Palæozoic plants, Dr. Scott adds a chapter on Mesozoic gymnosperms, in which special attention is directed to Mr. Wieland's able monograph of the remarkable silicified cycadean stems from America. In the clearly written account of these plants, emphasis is laid on the striking differences between their flowers and those of recent cycads, a difference which is necessarily somewhat obscured by the application of the term cycad to plants the reproductive organs of which differ *toto coelo* from those of the Cycadaceæ. The opinion held by several botanists that the results of Mr. Wieland's work afford a clue to the solution of the problem of the origin of the angiosperms receives due attention. Bearing in mind the scope of the "Studies," it would be unreasonable to find fault with the brevity of the section devoted to the past history of the Coniferales. In the admirable chapter devoted to general results, the author adopts a new grouping of the vascular plants, which he naturally speaks of as provisional. As knowledge increases, we conveniently record progress towards what we believe to be a closer approximation to a natural scheme of classification by means of changes in the arrangement of the subdivisions or by a redistribution of genera. Any change challenges criticism, but, whether accepted or not, it stimulates discussion and helps us to correlate our ideas. Bacon's aphorism, "Truth more easily comes out of error than out of confusion," may be applied to any honest attempt to express progress in knowledge by a re-adjustment of existing classifications. These words may seem to imply a disinclination to accept the views embodied in Dr. Scott's classification; they are quoted rather as an expression of gratitude for a contribution the value of which is to be measured, not by considerations of finality, but by the stimulus which it gives to wholesome criticism and to a broader survey of the facts at our disposal.

By the expansion of the "Studies," Dr. Scott has given a further incentive to students of plant evolution, and has produced a book which, in clearness of exposition, in scientific accuracy, and in soundness of judgment, it would be difficult to surpass.

A. C. Seward.

PISCINE MORPHOLOGY.

A Treatise on Zoology. Edited by Sir Ray Lankester, K.C.B., F.R.S. Part IX., Vertebrata Craniata. First Fascicle, Cyclostomes and Fishes. By E. S. Goodrich, F.R.S. Pp. xvi+518. (London: A. and C. Black, 1909.) Price 20s. net.

BOTH the author of this book and the editor of the "Treatise on Zoology" are to be congratulated on this, the latest addition to the series. The author is dealing with a subject with which he is thoroughly familiar, and to which he has contributed a large amount of important research. The whole plan of the book is carefully conceived and carried out, and we can only regret that the necessity to keep the size of the book within certain limits has made great concentration inevitable in dealing with many parts of the subject. However, references to more than five hundred original papers afford a guide to the student who wishes to amplify Mr. Goodrich's text.

This book is less a mere compilation than are most text-books, and the personality of the author is constantly felt. One of the chief features is the great number of excellent new figures, largely semi-diagrammatic representations of dissections, showing the three dimensions of space. Readers will be deeply grateful for this, for we have all experienced the annoyance of turning up text-book after text-book in the attempt to clear up some doubtful point, and finding the same figure, taken from some time-honoured authority, reproduced in all. How little the book before us suffers from this common failing is evident when it is said that more than a hundred and fifty of the figures are of the author's own drawing.

The subject is considered from a purely morphological and evolutionary point of view, to the almost complete exclusion of the physiological side, and the references to function are extremely few. While it is necessary in a book of limited length to discriminate between what to put in and what to leave out, one feels, perhaps, that in this case the fact that organs are functional parts of living animals has been kept too much in the background.

It is natural, and also desirable, that an author should treat at most length those parts of his subject to which he himself has given most attention, even at the expense of other portions. Here, many of the "soft-parts," for example, the nervous system, and the digestive organs receive rather scant attention. On the other hand, the supporting tissues, especially the exoskeleton and the skeleton of the median and paired fins, are admirably treated, and at considerable length.

The classification adopted differs in many respects from that found in contemporary text-books. The Pisces are divided into three great groups, the Chondricthyes, Ostracodermi, and Osteichthyes. The Chondricthyes include the Elasmobranchii (Selachii and Holocephali) and the extinct groups usually associated with them. The Osteichthyes are divided into two groups, the first including the Dipnoi and Coccosteomorphi, the second the Teleostomi. Useful phylogenetic trees are given at the beginning of the larger groups. In dealing with the Teleostei, use is freely made of subdivisions represented only by letters or numerals, thus saving the coining of new words—a most desirable proceeding in dealing with a provisional classification, such as that of the Teleosteans must at present be.

A few special points of minor importance call for criticism. On p. 11 we read that

> "Stöhr showed that, in the Urodela, the 'vertebral region' is developed from three distinct centres—the parachordal, the mesotic cartilage of the auditory capsule, and an occipital segment resembling a vertebra."

This is a very confusing use of the terms, neither in accordance with Stöhr's original usage nor with that commonly accepted at present. Stöhr divided the post-trabecular elements of the skull into three, the "Balkenplatte," mesotic cartilage, and occipital portion, and identified the *last* of these with Huxley's parachordals. The custom now is to use the word parachordal as including all these three sections. The student will have difficulty in reconciling Mr. Goodrich's use of the term with either of the other two meanings.

On p. 116 we read, as one of the *primitive* characters of the Pisces (which group here does not include the Cyclostomes), that the pericardium may communicate with the abdominal cœlome. In view of the fact that this communication in Elasmobranchs is formed secondarily in ontogeny after the two cavities have been completely separated from each other, it would have been better not to have included it in the list of characters "considered primitive" without a qualifying note.

"Occipital" (p. 239) hardly seems a happy name for the large dermal bone of the Dipnoi (Wiedersheim's fronto-parietal), which, indeed, roofs in the whole cranium in the Dipneumona.

Considering the book as a whole, we may say confidently that, in spite of the number of excellent text-books already available, Mr. Goodrich's work will be extremely welcome to the student of vertebrate morphology, as being both a trustworthy source of general information on the subject and in many points an epitome of recent research by one who has himself taken a most important part in it.

W. E. A.

FRENCH SYLVICULTURE.

Sylviculture. By Albert Fron. With an introduction by Dr. P. Regnard. Second edition. Pp. 496. (Paris: J. B. Baillière et Fils, 1909.)

MR. G. WERY, the sub-director of the Institut Agronomique, is the editor of the French "Agricultural Encyclopædia," which consists of sixty volumes, each containing 400—500 pages, copiously illustrated, and sold in paper covers at 5 francs each, or bound for 6 francs. The subjects dealt with are distributed under six headings, as follows:—

(1) *Cultivation and Improvement of the Soil.* General agriculture; manures.

(2) *Production of Plants.* Agricultural botany; cereals; fodder plants; garden vegetables, orchards, vines, diseases of cultivated plants. Fron's sylviculture comes under this heading.

(3) *Production of Animals.* Agricultural zoology; entomology and the study of animal parasites; farm stock; breeding and rearing horses; fish; bees; birds; game, &c.

(4) *Agricultural Technology.* Dairy farming; brewing; flour-mills; cider, wine; also agricultural chemistry in two volumes.

(5) *Rural Engineering.* Agricultural machines; motors; buildings; survey; drainage.

(6) *Rural Political Economy, and Law.* This comprises six volumes, including hygiene.

We have therefore a splendid series of cheap scientific books by professors and experts of agriculture and of the allied arts, and if the other subjects are treated as skilfully and thoroughly as Mr. Fron has dealt with sylviculture, the French landowners and farmers are thus endowed with an excellent, cheap, technical literature.

Mr. Fron is an inspector of the State forests, and professor of forestry at the National Forest School at Les Barres, where promising young forest guards are trained to become head-guards and forest officers in the State, communal, and private forests. The first edition of the book has been sold, and this new edition has extended the subject-matter, so as to form a concise, clearly-written book, suitable for the private landowner and his foresters. It is divided into three parts:—

(1) *The Forest and its Constituent Trees and Shrubs.* This gives an account of the life-history of a tree, and a description of its parts; a list of the native woody species of France, with their botanical characteristics, and the uses to which their timber may be put. Then come trees considered in groups, the effects of density of growth, or its absence, on their forms and on the soil. Different kinds of crops of trees, natural or artificial, indigenous or exotic, follow, and the effects of forests on the flow of water and on the soil of mountains are described.

(2) *Practical Sylviculture.* Methods of stocking the ground, artificial or natural. Human agency in its effects on forest soil and on tree-crops. Methods of felling. General ideas about working-plans (quite sufficient for the private owner). Cubage and combinations of woods. Daily work done by an average labourer in various operations. Protection of forests against man, animals (including insects), physical phenomena (fire, snow, gales, &c.); fungi, weeds, &c. Valuation of forests.

(3) Comprises a study of the types of forest that prevail in France and of their management.

The term *sylviculture* among French professional foresters means a limited part of forestry, dealing with the cultivations of forest trees, but not including valuation or working-plans. The author, being a professional forester, knows this well enough, but has extended the meaning of the term in the way it is understood by the French people, for, unfortunately, the latter have not adopted the old French term, "*foresterie*," which is more comprehensive than *sylviculture*, corresponding to our term *forestry*.

The book is well and logically written and up to date, and its forestry is quite sound, while the printing is well done, and though the plates are somewhat rough, owing to the smooth paper, they serve to illustrate the author's points, and he has performed his task in a masterly manner.

A book resembling Fron's sylviculture, dealing with British woodlands, is still a desideratum. Our works on forestry are either comparatively very expensive and above the heads of the estate forester, or are too sketchy and controversial to be real text-books. But it is doubtful whether any British author could afford to publish a book like Fron's at 5*s.* a copy, so as to place it within the reach of estate foresters. "Our Forests and Woodlands," by John Nisbet, costing 7*s.* 6*d.*, is still one of the best short accounts of British woodlands, and is beautifully though sparsely illustrated, but it does not possess the clear scientific arrangement, nor the completeness of Fron's book. "English Estate Forestry," by A. C. Forbes, as well illustrated as is Nisbet's book, costs 12*s.* 6*d.*, and though also an excellent book, is not sufficiently detailed to become an elementary text-book, nor does it give a satisfactory account of coppice-with-standards, which on the Continent is the only recognised method of producing large, broad-leaved timber other than beech that is within the range of private estate management.

W. R. Fisher.

PRACTICAL CHEMISTRY.

(1) *Exercises in Physical Chemistry.* By Dr. W. A. Roth. Authorised Translation by A. T. Cameron. Pp. xii+196. (London: Constable and Co., Ltd., 1909.) Price 6*s.* net.

(2) *Laboratory Methods of Inorganic Chemistry.* By Heinrich Biltz and Wilhelm Biltz. Authorised Translation by W. T. Hall and A. A. Blanchard. Pp. xv+258. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1909.) Price 12*s.* 6*d.* net.

(1) ACCORDING to the experience of the author of this laboratory guide to physical chemistry, the existing German works on the subject contain either too much or too little for the beginner, and he has, therefore, attempted to cater for the

student who is commencing to study the subject. To a large extent the book is based on the "Kleine Praktikum," arranged by Prof. Nernst for students of physical chemistry at the universities of Göttingen and Berlin. As such it presents many features of merit, but at the same time a lack of discretion in regard to the relative amounts of space devoted to the various sections of the subject detracts very largely from its value as a work for general laboratory use. Only nine pages, for example, are devoted to the chapter on chemical statics and dynamics, whereas twenty-two are taken up by that on the determination of density. Again, thermochemistry is liberally treated, while spectroscopic and electrolytic work are not dealt with at all. Apart from this lack of proportion, the subject-matter is carefully handled, and the exercises are in general well chosen. Special stress is laid on the application of physico-chemical methods in connection with quantitative analysis and the determination of the constitution of organic compounds. The translator has added a chapter on the construction and use of the thermostat, and also an appendix on the use of the electroscope in radio-active work.

(2) In consideration of the fact that preparative work in inorganic chemistry forms an essential part of the training of the modern chemical student, an addition to the rather scanty literature of the subject is not unwelcome. In this book the authors outline a course of laboratory work which is essentially synthetic in nature, and is designed to aid in acquiring a more adequate knowledge of inorganic chemistry than is to be obtained by practice in chemical analysis alone. It is intended primarily for those who have passed beyond the more elementary stage in their study of chemistry. Although this is the case, the experimental part of the book is set out in relatively complete detail, and, to assist in the study of the theoretical relations involved, brief discussions of a general nature are interspersed throughout the book.

The experiments, which involve the preparation of more than 200 substances, have been carefully compiled, and the processes have been tested in the authors' own laboratories.

Having regard to the meritorious nature of the contents of the book, it is unfortunate that the authors should have departed from the usual practice in the arrangement of their material. Instead of treating the compounds according to the periodic groups, they have chosen to base the classification upon the different types of combination. It is claimed that this arrangement results in a better comprehension of analogous methods of preparation and analogous properties, and a more intimate amalgamation of experimental and theoretical chemistry. The justice of this claim appears doubtful. On the other hand, the general impression created by the arrangement is that the experiments have been written down in haphazard order, with the result that closely related compounds are often widely separated. In these circumstances a re-arrangement of the material on the lines of the periodic table would add to the value of the book.

SCIENTIFIC METHOD IN GEOGRAPHY.

Macmillan's Practical Modern Geographies. (1) *A Geography of the British Isles.* By Dr. A. Morley Davies. Pp. xiv+358. Price 3*s*.

(2) *Practical Exercises in Geography.* By B. C. Wallis. Pp. xxiii+184. (London: Macmillan and Co., Ltd., 1909.) Price 2*s*. 6*d*.

(1) IN the "Geography of the British Isles," Dr. Davies introduces each section by a number of exercises with maps and statistics, so that pupils may have inferences of their own gleaning to help them to appreciate the descriptive portions of the book. This is an interesting experiment, and is carried out with considerable success, though chances are missed in the descriptive paragraphs which might have been used to teach rather more by appeal to the imagination. In that way, too, the work would have been made more valuable as a book for the pupils themselves to handle.

The subject is introduced through a brief survey of the British region as a whole, and then its tides and climate are considered, after which districts are studied in a regular sequence. It is characteristic of the district-study in this book that no attempt is made to define the districts in any exclusive fashion; they are chosen as geographical units, and the occasional overlapping only enhances the thoroughness of the survey.

London is of such unique interest, and shows in so many ways the influence of the past on the present geographical conditions that it might have been considered in more detail, especially from this point of view. A fuller account might also have prompted teachers in other centres to study their own towns in similar fashion, and thence to introduce local and practical considerations into their teaching. A large number of district maps and some good photographs, mostly illustrating physical features, enrich this book, and an alphabetical index of the abbreviated names used on the maps is a useful addition.

(2) "Practical Exercises in Geography" is a reasoned attempt to work out a continuous series of practical exercises, some of the nature of experiments, some "in the field," and some in the class-room. The course begins with the simplest rudiments of surveying, and leads up very effectively to the understanding of contour lines and the relief of the country, the United Kingdom being, of course, the chief object of study.

Following this are exercises on the factors of climate, and from the basis of the study of relief and of climate we proceed to vegetation and human activities. A less satisfactory chapter on rocks and minerals is inserted mainly for the purpose of drawing in the consideration of coal, iron, and other mineral products. The definition of metamorphic rocks as "rocks which were once 'water' rocks and have since been changed, usually by the action of heat," is objectionable.

The course should give a reasonable knowledge of British geography in a somewhat unusual fashion, but it is to be feared that the knowledge of other areas acquired here and there would not be satisfactory for any purpose unless woven into a more complete system by the teacher. An interesting experiment is the inclusion of additional exercises, which are based upon descriptions extracted from the volumes of the Highways and Byways Series. They are well chosen to illustrate the different types of English scenery, and should be a useful link between æsthetic appreciation and exact observation.

OUR BOOK SHELF.

Carburettors, Vaporisers, and Distributing Valves used in Internal Combustion Engines. By E. Butler. Pp. xi+176. (London: C. Griffin and Co., Ltd., 1909.) Price 6*s.* net.

MR. BUTLER has written an interesting book on a subject which hitherto has not had justice done to it; and he is to be congratulated upon his bold decision to devote a book exclusively to these matters of detail instead of compressing them into the small space that can be spared in books dealing with internal combustion engines in their complete form. It cannot, of course, replace the completer treatises, but it is an excellent adjunct to them and is evidently written by one who is thoroughly familiar with this side of the work.

The volume contains twelve short chapters, of which the first four are concerned with surface and spray carburettors for petrol and alcohol motors, carburettors capable of automatically adjusting the air and petrol supplies over a wide range of speed, and various types of vaporisers for use with the heavy oils forming the second distillate from petroleum. The remainder of the book includes descriptions of various forms of admission and exhaust valves used on all classes of internal-combustion engines, together with some discussion of methods of actuating, timing, and water-cooling them.

Mr. Butler is an inventor on these lines, and has made himself familiar with what others have done in the same field; thus there are illustrations of no fewer than fifty-two different kinds of carburettor and vaporiser. With so much study of these matters, we wonder to find that he is apparently unaware of the increasingly common practice with motor vehicles of using the heat of the exhaust gases to warm, not the mixture as a whole, but the air supply only. The warm air is then passed over the jet and all the other arrangements are as usual. At least equal economy is obtained in this way besides greater ease of fitting and a lowering of the prime cost. Even with so simplified a form of carburettor or vaporiser as this makes, it has been found that the cylinders do not require cleaning out at any more frequent intervals.

As regards the valve mechanisms, we are glad to find that the author has included a description of the Knight engine, and, further, that he has given a good deal of space to the discussion of sliding and rotary valves. We cannot but feel that the poppet type of valve is unlikely to be permanently used, and the author deserves our thanks for having taken us some steps along the road towards a better form of valve mechanism. Many motor manufacturers are working in the same direction, and there is no doubt that we shall soon be hearing of other suggested forms of valve. If the experience of extended use of the Knight engine is favourable, it will give great impetus to this development. With the largest forms of gas engine there are, of course, already many engines now running with complete success, using slide valve forms of control for either the admission or exhaust ports, or for both.

Cotton Spinning Calculations. By W. S. Taggart. Pp. xiv+335. (London: Macmillan and Co., Ltd., 1909.) Price 4*s.* net.

THE author of this excellent and beautifully printed text-book assumes that the reader has no special equipment beyond an elementary knowledge of arithmetic, and some acquaintance with the various processes of cotton manufacture and the technical nomenclature used in connection therewith. In the introductory chapter, he gives general calculations respecting the velocity ratio in wheel trains and belt gearing; the surface velocities of rollers and the stretching of fibres resulting from "draft"; the estimation of "hanks" and "counts"; and the force actions of levers. A set of exercises closes this part. In succeeding chapters the treatment is more direct and special. The various machines through which the material passes, from the Scutcher to the Ring Spinning Frame, are considered in detail. The author has had the assistance of the leading manufacturers of textile machinery in the cotton district, and is thus able to give diagrams, drawings, and tables of wheel teeth, showing very clearly with full details the mechanisms used in all the standard types of machines. The calculations are therefore based on numbers representing the best modern practice. A special chapter is devoted to the consideration of epicyclic or differential gears and the design of cone drums. Thus, by repetition, and by the wealth of illustration provided, no reader should fail to obtain a thorough insight into the action of the most complicated of the mechanisms. This kind of quantitative work is essential if a student is to have anything more than a superficial knowledge of the subject, and it will enable him readily to calculate the wheel changes, &c., necessary in order that a machine shall be able to cope with the varying demands made upon it.

The author concludes his very interesting volume with a number of useful tables and an index. Both author and printers are to be congratulated on the production of this admirable work, which should be in the hands of everyone, at home and abroad, who is interested in the practical working of textile machinery.

Proceedings of the Aristotelian Society. New series, Vol. ix. Pp. 259. (London: Williams and Norgate, 1909.) Price 10*s.* 6*d.* net.

OF the nine articles contained in this volume the most important are, perhaps, Prof. Alexander's essay on "Mental Activity in Willing and Acting," and Prof. Stout's rejoinder, "Are Presentations Mental or Physical?" The point at issue in these papers is one of fundamental importance for both psychology and the theory of knowledge, since Prof. Alexander's contention, to put it quite plainly, is that all mental activity consists solely of conation and feeling, or possibly, since it is conceivable that the feeling or affective side of mental life may be reducible to experience of successful and thwarted conation, of conations alone. Hence he refuses to admit the existence of such cognitive processes as have usually been supposed to be denoted by the names sensation, imagination, perception. On his view the *object* apprehended in all these processes is physical; the *process* involved is simply conation directed towards a specific physical object. It follows, of course, that if Prof. Alexander makes out his case, "presentations" must be deleted entirely from our account of the stuff out of which mind is made, and, in the theory of knowledge, any doctrine which assumes either that "we can only know our own sensations," or that, at any rate, we begin by knowing our sensations and have to infer from them the character of the physical realities which are their stimuli, must be erroneous. Prof. Stout's criticism appears to show that Prof. Alexander's doctrine cannot be sustained as it stands, but the fact that it can be put forward by a writer of such philosophical eminence is an interesting sign of the influence which Avenarius is at last beginning to exercise on British philosophy.

Very similar tendencies are revealed by Mr. A. Wolf's interesting paper on "Natural Realism and Present Tendencies in Philosophy." The interest awakened by Bergson's striking book "L'Évolution Créatrice" is witnessed to by Mr. Carr's disquisition on Bergson's theory of knowledge, and Mr. G. T. R. Ross's treatment of the satisfaction of thinking. Pragmatism, as one would expect, does not go unrepresented. Dr. Schiller inflicts one of those castigations which are becoming periodical with him on rationalism in a paper on "The Rationalistic Conception of Truth," and the subject also figures prominently in a so-called symposium on pluralism, in which different points of view are represented by Dr. Schiller, Prof. Muirhead, and the writer of this notice. The volume further contains an essay on "The Mutual Symbolism of Intelligence and Activity," by Mr. Foston, and a discussion between Prof. Bosanquet, Dr. Sophie Bryant and Mr. G. T. R. Ross on "The Place of Experts in Democracy."

A. E. TAYLOR.

An Introduction to the Study of Biology. By J. W. Kirkaldy and I. M. Drummond. Pp. iv+259. (Oxford: Clarendon Press, 1909.) Price *6s. 6d.*

THIS little book represents an attempt to deal, within the limits of some 250 pages, with the study of biology as exemplified primarily by the organisms prescribed in the syllabus of the Oxford and Cambridge Schools' Examination Board. The authors have, however, realised the deficiencies of the type system and endeavoured to "bridge over the gulfs" by brief accounts of, or references to, a considerable number of forms "allied" to the selected types. Thus Monocystis, Hæmamœba, Bacillus, Chromulina, Actinosphærium, Globigerina, Rhaphidococcus, Arcella, Euglena, Noctiluca, Stylonichia, Acineta, Desmids and Diatoms are all introduced as allies of the more familiar Protozoa, viz. Amœba, Saccharomyces, Sphærella, Vorticella and Paramœcium.

There is no doubt that a too rigid adherence to the type-system does produce a very disconnected idea of the animal kingdom, but we fear that the ordinary schoolboy will think that it is bad enough to have to make the acquaintance of the types without having to shake hands with so many of their relations. No fewer than sixteen types of animals and plants are dealt with in more or less detail, ranging from the Amœba to the dogfish, and from the yeast to the sunflower, besides chapters on the distinction between animals and plants, the life-history of the frog, and the physiology of the rabbit.

The book contains numerous illustrations, for the most part borrowed from very familiar sources; a few are original, but we cannot congratulate the authors very warmly upon these. The picture of a crayfish on p. 112 is extraordinarily crude. The book gives an enormous amount of information gathered from a very wide field, but it is far too concentrated to be inspiring, and the authors do not appear to have succeeded in putting the general principles dealt with in a very clear light. We hope it is intended to be read in connection with a course of practical work, but we have not been able to find any reference to the necessity for such a course.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The End of the *Beagle*.

IT is well known that Charles Darwin began to advocate his famous doctrine of evolution after his voyage on board H.M.S. *Beagle* as naturalist, in the course of which he went to South America, Africa, and Oceania, and founded the theory of natural selection; but it has been a matter of regret among men of science throughout the world that the famous old ship had passed out of sight. As the result of careful inquiries, however, by Mr. Shigetaka Shiga, a renowned geographer in Japan, it has now been ascertained what was the ultimate fate of the *Beagle*.

Mr. S. Shiga has told the story to the editor of the *Yorodzu Chōhō*, the most popular newspaper in Tokyo, as follows:—"While I was attending the Sapporo Agricultural School some twenty years ago, I read in the *Living Age*, an American literary magazine, that the *Beagle* had been sold in Japan. After my inquiry it was found out that the warship had been bought by the Lord Shimadzu, who had changed its name to *Kenkō-maru*. Afterwards it was purchased by the Naval Department, and kept as a training ship of the Naval School in Tsukiji, Tokyo; but I had then no intention of preserving the famous ship, and so took no notice of the matter.

"This spring I heard Englishmen were sorry at having lost all trace of the *Beagle* at the hundredth anniversary of the great naturalist's birth. I then applied to a steward of Prince Shimadzu, as well as Viscount Captain Ogasawara, to get fuller particulars of the ship. According to the record of the Prince, the *Kenkō-maru* was certainly the *Beagle* that had been built of teak at Liverpool; it was bought for 75,000 dollars in Nagasaki on July 23 in the first year of Gwanji (1864 A.D.). Viscount Ogasawara informed me of the same fact, and added that the Naval Department ordered several officials, Kawamura (the late Count Sumiyoshi), Masuda, and Satō, to receive the same ship from the Shimadzu clan at Shinagawa on June 13 in the third year of Meiji (1870). It was in existence as a training-ship in the thirteenth year (1880), and was re-named *Yeiji-maru* at Yokosuga in the fifteenth year (1882). It was in May of the twenty-second year that the ship was sold by auction for 3276 *yen* to the late Kikusaburo Oaki, the proprietor of the Oaki Ship-building Yard.

"After some inquiries about the *Yeiji-maru* at Oaki's, I learned that the ship had been broken up at the old Shinagawa Fort, and that her cabin had been preserved for three years, when it was lost sight of; but Mr. Keizo Oaki, the present owner, who superintended the breaking up of the ship as the engineer-in-chief, has had the kindness to make inquiry of the workmen engaged in the work. The result is as follows. A part of the ship was at length discovered. It was being used as a stand for stones which have been piled up near the temple of Suitengu, in the premises of the dockyard. Having been taken out, it was found to be a part of the ribs of the *Beagle*, 3·5 feet in length, 1·5 feet in breadth, and of teak. Thus a portion of the fragments of the famous *Beagle* has at last been found."

TOYOZI NODA.

Ichinoseki, Iwate, Japan, October 27.

The Maintenance of Forced Oscillations of a New Type.

IN a paper "On a Class of Forced Oscillations" published in the *Quarterly Journal of Pure and Applied Mathematics* (No. 148, June, 1906), Mr. Andrew Stephenson discussed mathematically a proposition which may be stated in his own words thus: periodic non-generating force acting on a system in oscillation about a position of stable equilibrium exerts a cumulative action in intensifying or diminishing the amplitude, if its frequency is contained within any one of a number of ranges lying in the vicinity of 2μ, $2\mu/2$, $2\mu/3$ . . ., where μ is the natural frequency of the system.

Further investigations upon this and other allied subjects appear in seven subsequent issues of the *Philosophical Magazine*. As regards the forced oscillations discussed in the *Quarterly*, the author gives, in the way of experimental verification of his mathematics, the following:—the influence of the disturbing motion becomes feebler as r increases, but it may easily be observed experimentally in a number of cases. For this purpose suspend a load by means of a spiral spring, and attach to it a pendulum light compared with the load, but of such density that the air resistance is negligible; the pendulum being of suitably chosen period, it will be found that when the load is carefully adjusted the relative equilibrium of the pendulum in the vertical motion is unstable.

I believe the beauty and interest of the results obtained by Mr. Andrew Stephenson have not been generally realised, otherwise it is nearly certain that something more satisfying in the way of experimental demonstration of these oscillations than mere observation of "instability of equilibrium" in certain cases would have been put in the field. I think an experimentalist would hardly be pleased with anything less than the actual permanent maintenance of oscillations of the type mentioned, *i.e.* something similar to the experiments of Faraday, Melde, and Lord Rayleigh for the case of double frequency, which, as Mr. Stephenson points out, is only one particular case of his general theorem.

During the course of certain acoustical work which I have been engaged in during the last two years, I observed certain types of stationary vibration which I find are undoubtedly of the kind contemplated in Mr. Stephenson's paper. These observations were made with an apparatus from which any new effects were apparently hardly to be expected. The arrangement was the well-known one of a string maintained in vibration by a tuning-fork oscillating in a direction parallel to the string. It is generally supposed that the oscillations permanently maintained have a frequency which is half that of the tuning-fork. I found this was *not* always the case. With an electrically maintained tuning-fork the amplitude of oscillation of which could be readily adjusted, the stationary oscillation of the string had a frequency of $\frac{1}{2}$ of, equal to, 3/2 times, twice, &c., that of the tuning-fork, each term in the harmonic series appearing separately by itself with a fairly large amplitude, or with one or more of the others conjointly, according to circumstances. The frequency- and phase-relations could be studied by several methods, most of which were very simple applications of the principle of Lissajous's figures.

The possibility of isolating the harmonics, and also certain serious discrepancies between theory and experiment as regards the phase of the oscillations in the case of double frequency, were traced to the existence of variations of tension in free oscillations of sensible amplitude. These variations of tension were experimentally demonstrated by a special form of monochord denominated the "Ectara" (*vide* the Journal of the Indian Mathematical Club for October, pp. 170–5), in which the sounding surface is a membrane perpendicular to the vibrating string, and emits a tone having *twice* its frequency.

Post-Box 59, Rangoon. C. V. Raman.

Absorption-bands in Colourless Liquids.

In the obituary notice of the late Dr. W. J. Russell, F.R.S. (Nature, November 25, p. 101), whose genial friendship I enjoyed and with whom, when occasionally in London, I had friendly intercourse, it is stated that he had published "papers conjointly with Mr. Lapraik on absorption spectra, and notably one on the absorption bands in the visible spectra of colourless liquids, which was the pioneer paper in a branch of inquiry that has been ably followed up by Prof. Noel Hartley, F.R.S., Mr. E. C. C. Baly, F.R.S., and others." It seems ungracious to call in question the accuracy of this reference, and I feel, indeed, a great inclination to let it pass without comment, although it is incompatible with authoritative statements made elsewhere; but, inasmuch as the passage is liable to be reprinted without question and repeated in other publications, I consider it would be better to invite the writer's attention to the Chemical Society's Transactions, xxxix., 153–68, 1881, "Researches on the Relation between the Molecular Structure of Carbon Compounds and their Absorption Spectra," and suggest that he should compare it with the paper which follows in the same volume, pp. 168–73, "On the Absorption-bands in the Visible Spectrum produced by Certain Colourless Liquids." Having done so, I think he will agree that not only is the latter not the pioneer paper, but also that there is very little in common between the two. In fact, the latter communication is more closely allied to the work of Abney and Festing in the infra-red region, a work to which the authors themselves make a special reference.

W. N. Hartley.

Royal College of Science, Dublin, November 30.

The Inheritance of Acquired Characters.

In his review of Prof. Poulton's work, "Charles Darwin and the Origin of Species," Prof. Meldola says (Nature, November 25, p. 92) that the Darwinian theory is absolutely dependent upon the truth of the belief "in the transmissibility by inheritance of individual differences or 'fluctuations.'" This is undoubtedly true. There is now available a vast amount of evidence tending to show that "fluctuations" seemingly the direct results of changes in the environment are inherited; but how is it possible to convince Weismann and his followers that such "fluctuations" have not been due, as they will say, to "spontaneous germinal variations"? Surely the *onus probandi* really rests with them!

We have here the question of the inheritance or not of acquired characters reduced to its simplest terms. There is much and very varied evidence to show the influence of changes in the environment in producing "fluctuations" which are heritable, but what evidence can those who disbelieve in the inheritance of acquired characters present to show that in all such cases there *must* be a primary germinal change? H. Charlton Bastian.

The Athenæum, November 26.

Luminous Night Clouds and Aurora Spectrum.

On the evening of Friday, December 3, there occurred a very brilliant display of luminous night clouds in rather peculiar circumstances. During the earlier part of the evening the sky had been clear, and no indications of an aurora were observed. About 10.15 p.m. the sky became completely overcast quite suddenly, and it was noticed that this appeared to be by general formation of haze *in situ*, and not by the drifting of clouds. Almost immediately after this numerous patches of light cloud appeared, travelling with considerable velocity eastward. From numerous previous experiences it was at once apparent that these were not ordinary cloud forms, and the moon was not high enough to account for their extreme brilliancy. Careful examination with a hand spectroscope confirmed the surmise that they were luminous clouds, the green auroral line being very bright and sharply defined; on several of the brighter masses other lines were suspected, but not sufficiently well to assign any position. These observations were confirmed by Mr. W. Moss. At about 10.45 p.m. the clouds gradually became less frequent, and the sky became clear again almost as suddenly as it had been overcast.

It will be of interest to hear if any magnetic storm has been recorded for this epoch. The surface of the sun has been in continued disturbance during the past week, as evidenced by the rapidly changing forms of numerous spots. One of the largest groups would be passing round the north-west limb. Charles P. Butler.

Solar Physics Observatory, London, S.W.

Coloration of Birds' Eggs.

Some time ago I wrote a short letter asking for information about the colours of birds' eggs, which appeared in Nature of May 14, 1908. I read the answer to my letter in a subsequent number of Nature, which, unfortunately, did not appear to me to throw much light on the subject.

I would like to suggest that this colouring of eggs was in some way originally analogous to the change of colour observable in the chameleon and certain lizards, though by no means at the same level of development. Although it is quite possible that the colouring in some cases is protective, or has become so, it does not seem that this is a fixed rule. Why should the egg of a starling, which generally builds on house-tops, be blue? The hedge-sparrow's, again, is blue, while the thrush's is blue spotted with black, and the blackbird's is green, though the position of their nests is vastly similar. Again, on examining the excellent "clutches" at the Natural History Museum which exhibit the additional cuckoo's egg, one is struck by the variation in shade, which, according to observers, is matched by the bird itself.

It seems to me that the elucidation of this problem would be of great value in such vexed questions as the inheritance of acquired characteristics, and might be really illustrative of the exact processes of evolution. R. L. LESLIE.

13 Electric Mansions, Brixton, S.W., December 1.

The Terminal Velocity of Fall of Small Spheres in Air.

AT the recent Winnipeg meeting of the British Association we presented some results on the terminal velocity of fall of approximately spherical spores, which were not in agreement with Stokes's formula (see NATURE, October 14, p. 472). We have succeeded since in making minute spheres of paraffin wax, a certain black wax, and mercury, and have determined their terminal velocities over a wide range of sizes by the same method as in the preceding investigation. The velocities obtained for these spheres are in close agreement with Stokes's formula. The reason for the deviations in the former cases is not clear.

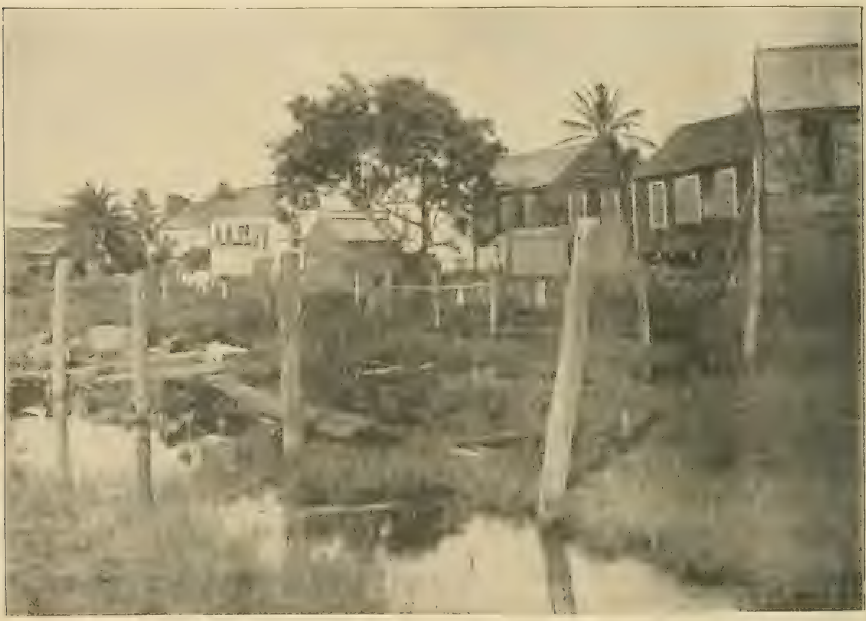

FIG. 1.—Water-logged Anopheline Breeding Land, Belize. From "Mosquito or Man?"

THE PROPHYLAXIS OF TROPICAL DISEASES.

THE history of tropical medicine, or what might be called its recent twentieth century renaissance, will go down to posterity as one of the most remarkable chapters in medicine. In a book entitled "Mosquito or Man? The Conquest of the Tropical World,"[1] Sir Rubert Boyce endeavours, in his own words, to epitomise this wonderful movement, a movement initiated in England by the then Secretary of State for the Colonies, Mr. Joseph Chamberlain, and by Sir Patrick Manson, a physician who had practised in the East, and had returned home imbued with the idea that the diseases of the tropics stood, so to speak, by themselves, and thus required special teaching in the medical schools of this country. The idea gained ground; two tropical schools, one in London, one in Liverpool, were founded, as Sir Rubert describes in his first chapter, and from that day onwards things have never looked back. Discovery after discovery have poured from these schools until now we stand on the threshold of a new world, a tropics as healthy as a temperate clime.

There apparently is nothing new under the sun, not even in medicine; the author describes in his fourth chapter how Sir Henry Blake, when Governor of Ceylon, had been shown a medical work written fourteen hundred years ago, in which the mosquito was stated to be a carrier of disease, and in which malaria was described as being transmitted by flies or mosquitoes—a truly prophetic utterance. More recently than this certainly, but yet, as things go now, of older times, Beauperthuy, in 1853, practically said the same thing, and had he but had a disciple of the worth of Ross the thing would have been settled long ago, and the gain to humanity have been the saving of millions of lives. Unfortunately, neither he nor King nor Finlay could prove the truth of their assertions, so it was left for Manson to revive the view once again, and this time at last a worker—Prof. Ross—came forward, and by a brilliant piece of research work solved the mystery once and for all. Long before this, Manson had also shown that the *Filaria bancrofti* underwent a metamorphosis or development in the tissues of a mosquito, and Low had subsequently proved—not Manson, as the author erroneously states on p. 36—that after this development was complete, the parasites found their way into the proboscis, and so got back to man when the insect bit again.

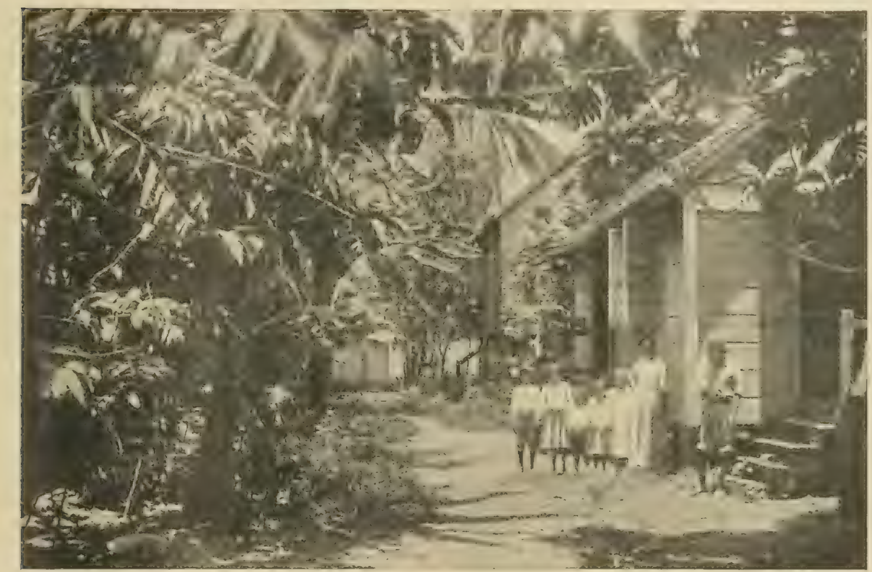

FIG. 2.—Too much Bush. Georgetown, Demerara. The effect is to obscure Sunlight and Fresh Air. From "Mosquito or Man?"

The Americans in Havana, profiting by Ross's work on malaria in the mosquito, tried mosquitoes for yellow fever, and by a series of experiments proved that a mosquito, the *Stegomyia calopus*, is the sole agent in the transmission of this disease. Here, then, were three of the most important tropical diseases clearly proved to be carried by mosquitoes, and, the cause having been ascertained, there only remained the question of prevention. How difficult it is to break down old traditions, and the antagonism that was displayed to the men of science who were sent out to preach the new doctrines are well brought out in chapter iii.; even to the present day there are members of the medical profession who disbelieve in the mosquito, *vide* p. 118. Ross at once, after his researches on the development of the malarial parasite in the mosquito, advocated a war against these insects as being the rational method of cutting the cycle and stamping out the disease, and his original campaigns and subsequent ones—Ismailia, for example—are samples of what may be done. He has complained at times of the slowness with which this new sanitation has moved in some of the British Colonies, and certainly, as compared with American dependencies, it has been slow; but now, as chapters viii. and xiv. of "Mosquito or Man?" show, the movement is advancing, most of the West Indian islands, terrified by the fear of yellow fever, the scourge of these parts, having now got definite ordinances and regulations dealing with the question of breeding grounds of mosquitoes.

The historical survey of yellow fever contained in chapter xi. gives an idea of what these places were like in the old days, Fergusson telling how 1500 soldiers had perished in one epidemic, while in another instance the Secretary for War in England wanted to know from the Governor of British Guiana why in a few months 69 per cent. of the white troops had perished. The churchyards of Barbados and the other islands are full of the bones of the victims, and it is said of the slopes of the Morne in St. Lucia that there is not a square yard without the remains of a soldier under it, more being there from the results of yellow fever than from the bullets of the enemy. Now what do we find? Let us refer to chapter xiv., which contains an account of the anti-yellow fever campaign in Havana, 1900. As Sir Rubert says, "This will always remain one of the first and one of the greatest examples of what has been done to stamp out a disease by concerted intelligent action, and using the latest and most modern weapons. When the American Government took over the administration of Cuba, one of the first things to be done was to make Havana a livable place. Hitherto it had been notoriously unhealthy, 35,952 persons perishing of yellow fever between the years 1853–1900, this being equivalent to 754 a year, 64 a month, or to 2 deaths a day;

and now, after General Woods, Colonel Gorgas, Guiteras, Finlay, and others took the situation firmly in hand, and organised a thoroughly efficient sanitary administration and a special raid upon the breeding places of the Stegomyia, the death-rate for Cuba has come down to between 11–17 pro mille. In 1907, only one case of yellow fever was reported in Havana."

Panama, New Orleans, and every other place treated in a like manner have given similar results, and certainly no sane individual will be found who, after reading "Mosquito or Man?" will deny that the mosquito is the only transmitter of yellow fever, and the remarkable results that follow its destruction.

Equally remarkable are the results that follow the extermination of anophelines for malaria. It was computed that Ismailia (p. 65), already mentioned, in 1886 had every inhabitant infected. Ross began his anti-malarial campaign there in 1901; by 1904 the cases were diminishing fast, until in 1905, 1906, 1907, and 1908, there were no new cases at all, indicating that the disease had been entirely stamped out. One would like to multiply further examples, but space forbids; those desiring more must read the book for themselves. There is little to criticise adversely in the work. Of omissions one might notice what was the first anti-malarial and yellow-fever campaign in the West Indies, namely, that conducted on the Morne and Vigie in St. Lucia in the year 1901, and also the pioneer work done on the destruction of mosquitoes for filariasis in Barbados.

Of errors, on p. 128, in the sentence "then after a latent period of three days the Stegomyia," &c.—should manifestly read "thirteen" days. On p. 133, "Man suffering from yellow fever after the fifth day is the reservoir" should read "Man suffering from yellow fever on the second or third day or before the fifth is the reservoir."

The book is clearly and ably written, is most interesting to read, is nicely illustrated by beautiful photographs, and we cannot do anything but praise the author for its production.

INDUSTRIAL EDUCATION.

TECHNICAL education may be regarded as falling naturally into two main divisions, (1) the education of the higher ranks of those engaged in industrial work, and (2) the education of the rank and file. From time to time one or other of these divisions occupies the more prominent place in the public interest. Recently, probably as a result of the discussions following the publication of the reports of the Poor Law Commission, special prominence has been given in the Press and elsewhere to the problem of the industrial education of those who will become in the near future the skilled workmen, artisans, and craftsmen of this country. Two recent attempts to influence public opinion in this matter may be here briefly recorded. Probably the more useful of the two is an attempt to organise a National Industrial Education League, the main object of which, in the language of its promoters, is "to make elementary education go hand in hand with industrial training, and to stop the criminal waste of the nation's best asset by giving our boys, before leaving school, a sound elementary industrial training." This proposal "has already received the approval of fifty-seven trades' councils, and of the representatives of 3,000,000 of industrial workers." In addition, promises of support have been received from many large employers of labour, distinguished educationists, and well known public men. Special stress is laid upon the fact that, "while the present system of technical education has benefitted many, it has left uncared for, and can never reach, the bulk of the children who are destined to become industrial workers."

The second recent noteworthy attempt to arrive at some definite agreement in the matter was a conference held on Friday, December 3, at the Mansion House, at the invitation of the Lord Mayor, to consider (1) the development of industrial training in both elementary and trade schools, and (2) the organisation of facilities for bringing boys and girls who are leaving the public elementary schools into better touch with the openings that exist in the industrial and commercial world. The conference was attended by a number of representatives of the London County Council Education Committee, many large employers of labour, and delegates from trades unions. It is probable that the London County Council, at whose suggestion the conference was called, will not profit much by the deliberations of the conference. As no definite resolutions were submitted for discussion, there was a tendency to neglect general principles and treat side-issues only. Running throughout most of the speeches, however, was a belief in the impossibility of reviving the old system of apprenticeship and the consequent necessity for some form of educational work to give the necessary industrial training formerly supplied by the apprenticeship system.

Interest in industrial education is now extending to the political parties. Thus the National Union of Conservative and Constitutional Associations, at its recent annual meeting in Manchester, passed a resolution urging

> "that the Conservative leaders at once push forward a scheme of development of technical, scientific, and agricultural education for Great Britain and Ireland, and that this scheme must be linked with the system of primary education."

On the other side of the political platform, the Labour party has passed resolutions at recent conferences demanding a free national system of primary, secondary, university, and technical education. At the forthcoming annual conference of the Labour party to be held in January, 1910, the conference will be asked

> "to observe the increasing tendency to make use of boy and girl labour in monotonous and uneducational industrial work as fatally destructive in its results upon the health, character, and subsequent industrial efficiency of the boys and girls themselves . . . and to urge upon the Government the desirability of so amending the Factory and Education Acts as to secure to every boy and girl between the ages of fourteen and eighteen efficient physical and technical training."

As the question of industrial education is one which affects the working classes more than any other section of the community, it is obvious that any future legislative action on the matter will be considerably influenced by expressions of opinion from bodies such as the Labour party and the trades unions. There is a danger that organisations of this type may be tempted to use their influence to give an unduly utilitarian bias to the education of boys and girls in the elementary and continuation schools. This danger is, however, more apparent than real, as is shown by (1) the vigorous support given by trades unions and similar bodies to the Workers' Educational Organisation, the object of which is to secure university education in literature, history, political economy, and the like for working men, and (2) the general undercurrent of opinion among workmen that the financial benefits of trade and technical education will ultimately fall to the employer and not to the workman.

At the present time much controversy is taking place respecting the question of apprenticeship. Is it desirable to revive the system of apprenticeship, and if desirable, is it possible to do so? The general trend of opinion at the present time is that, except for certain isolated trades, a revival of the apprenticeship system is both undesirable and impossible. Apprenticeship gives manual dexterity, but not the general industrial knowledge and intelligence which will enable the boy to adapt himself to changing industrial conditions. Hence it is desirable to make the necessary provision for compulsory education in the principles of different trades. The chief suggestions for effecting this are as follows:—(*a*) that the "leaving age" should be raised to fifteen years, the later years of school life being given partly to continuing the general education of the boy or girl, and partly to manual, scientific, and industrial work; (*b*) the establishment of "trade schools" for boys of from thirteen to sixteen years, giving about fifteen hours per week to class-room work in science and English, and about fifteen hours per week in the workshops; (*c*) compulsory attendance, for about twelve or more hours per week, at day or evening continuation schools for all young persons engaged in industrial work.

The movement for the spread of industrial education among the mass of the population of this country merits the support of the scientific world because of its bearing upon the general intellectual development of the nation as a whole, if that industrial education be framed upon sufficiently broad and generous lines. National progress, whether industrial or scientific, depends upon two main agencies—the organiser or leader and the skilled subordinate. University and higher technical education will produce the first of these, but the second will only be forthcoming in sufficient quantities through the operation of a broad general scheme of industrial education.

J. WILSON.

NILOMETRY.[1]

IT is the common fate of the ancient gods of flood and field in these sternly practical days to find their empires gone, their sceptres dishonoured, and even their personal liberty endangered. The Nile is no exception to the rule. The old age of the river of Egypt finds his fitful temper curbed, his moods controlled,

> ". . . all his faults observed,
> Set in a note-book, learned and conned by rote."

Where he was master, he has become a slave. Where he ruled, he must now learn to obey.

Such are the reflections induced on turning over the pages of a report, recently issued by the Egyptian Survey Department, dealing with the measurement of the water discharged by the Nile. The patient, persistent efforts of a Governmental bureau are gradually transforming the excesses of a capricious river into quiet and orderly processes adapted in every way to the agricultural needs of the country through which it flows. The construction of the Aswan Dam constituted the first great epoch-making achievement in this direction, and it is being followed up by a series of systematic observations of the regimen of the river which will throw light upon many obscurities in its phenomena, and enable further steps to be taken for its improvement.

The Nile, as is now generally known, is fed almost exclusively by the rain which falls over two elevated areas, the equatorial plateau of Central Africa and the Abyssinian plateau. These two sources act in very different ways, the first affording a relatively small but continuous supply, and the latter, copious but intermittent increments, producing the regular flood effect upon which, until quite recently, the agricultural prosperity of the country depended.

The admeasurement of the variation in the volume of water which is thus discharged necessitated the establishment of a gauging station, and the report states that, on grounds of expediency, a site was chosen at Sarras Old Fort, a little above Wadi Halfa. Here the necessary plant and apparatus were installed. It would take too long, however, to recapitulate, even succinctly, the dispositions which were made and the manner in which various local obstacles were overcome. These were duly related in the report, and the results of the observations taken are tabulated in part ii. of the volume. They include the mean velocity and cross-sectional area of the stream on successive dates, also a chemical analysis of the water and the percentage of mud in suspension. A third section gives a brief mathematical account of various rating formulæ for current meters.

[1] "Measurement of the Volumes Discharged by the Nile during 1905 and 1906." By E. M. Dowson, with a Note on Rating Formulæ for Current-meters, by J. I. Craig. Egyptian Ministry of Finance. Survey Department Paper, No. 11. Pp. 82. (Cairo: National Printing Department.) Price 100 millièmes.

NOTES.

WE regret to see the announcement of the death, on December 5, of Prof. H. Bauerman, at seventy-five years of age. The funeral will take place at Brookwood Cemetery on Friday, ember 10.

PROF. A. C. SEWARD, F.R.S., professor of botany in the University of Cambridge, has accepted the invitation of the executive committee of the Yorkshire Naturalists' Union to be president of that society for the year 1910.

THE council of the University of Paris has, we learn from the *Revue scientifique*, passed a resolution to the effect that monuments intended to commemorate men who have brought distinction on the University of Paris since 1808 shall be erected in the church of the Sorbonne. This honour will be awarded on the decision of the council, by a majority of two-thirds, not earlier than ten years after the decease of the person concerned.

WE notice with regret the death of Dr. Jean Binot, on November 25, at the age of forty-two years. Dr. Binot had charge of one of the laboratories of the Pasteur Institute of Paris. Before taking up the study of bacteriology he was associated with astronomy. In 1901 he had charge of an expedition for the study of the transit of Venus, and in connection with this work he was awarded the Janssen prize of the Paris Academy.

AN appeal is being made to the Treasury for funds to complete the publication of the scientific reports of the voyage of the *Scotia*. It appears that the Scottish expedition is the only one of the recent Antarctic expeditions—British, Belgian, German, French, Swedish, and Argentine—that has not received Government help. The appeal is made by the committee of the Scottish National Antarctic Expedition through its honorary secretary, Mr. J. G. Ferrier. An additional grant is asked for beyond the funds for publication, to enable Dr. Bruce to reimburse those who have advanced money beyond their regular subscriptions to the expedition.

THE following are among the lecture arrangements at the Royal Institution before Easter:—Mr. W. Duddell, a Christmas course of six illustrated lectures on modern electricity, adapted to a juvenile auditory: (1) first principles; (2) electrical instruments; (3) Röntgen rays; (4) the generation of electricity; (5) electric oscillations; (6) electric lighting; Prof. W. A. Herdman, three lectures on the cultivation of the sea; Rev. C. H. W. Johns, two lectures on Assyriology; Prof. F. W. Mott, six lectures on the emotions and their expression; Prof. Silvanus P. Thompson, three lectures on illumination, natural and artificial; Sir J. J. Thomson, six lectures on electric waves and the electromagnetic theory of light. The Friday evening meetings will commence on January 21, when Sir James Dewar will deliver a discourse on light reactions at low temperatures. Succeeding discourses will probably be given by the Rev. Canon Beeching, Prof. W. Bateson, Mr. C. E. S. Phillips, Prof. H. H. Turner, Lord Rayleigh, Dr. C. Chree, Dr. H. Brereton Baker, Sir J. J. Thomson, and other gentlemen.

The death is announced of Dr. T. Nishikawa, of Tokyo, for a number of years an associate of Dr. Kishinouyé in the Imperial Fisheries Bureau in Tokyo, and later a special investigator of pearls. Writing in *Science*, Prof. Bashford Dean says that Dr. Nishikawa was distinguished as the discoverer of a process by which the pearl oyster may be caused to secrete spherical pearls. Before this only hemispherical pearls had been produced, in spite of centuries of experimentation, especially in the Orient. Dr. Nishikawa devoted nearly ten years to his studies on producing pearls, and achieved success only in the days of his final illness. In his memory, and in token of the importance of his discovery, a number of his living pearl oysters were taken to the University of Tokyo on the occasion of the late graduation ceremony; they were opened in the presence of the Emperor, and Prof. Iijima demonstrated that their mantles had secreted spherical pearls. The publications of Dr. Nishikawa include important contributions to our knowledge of Japanese fishes, structural, systematic, and embryological. Especially to be recalled is his pioneer paper on the development of the remarkable frilled shark, *Chlamydoselachus anguineus*.

The Dick Institute, Kilmarnock, a gift to his native town from the late James Dick, of the Greenhead Gutta-percha Works, Glasgow, was destroyed by fire on the evening of November 26. The building, which cost about 15,000*l*., consisted of a public library and museum. The latter contained the very valuable collection of Carboniferous fossils which belonged to the late James Thomson, of Glasgow; a splendid collection of silurians, antiquities, &c., presented by the late Dr. Hunter-Selkirk, of Braidwood, Lanarkshire; and a very handsome collection of native birds presented by the Kilmarnock Glenfield Ramblers' Society, together with numerous other articles of great scientific value. Mr. H. Y. Simpson, librarian of the institute, informs us that the whole of these have been destroyed by the fire, and the loss is looked upon as irreparable, particularly so in the case of the Thomson collection of corals and reptiles, many of which were type-specimens, and therefore regarded by geologists as quite of incalculable value.

The annual general meeting of the Royal Agricultural Society of England was held on December 8, when various reports, including that of the council, were considered. The council's report shows that the total number of governors and members on the register is 9920. The show of 1910 will take place in Liverpool on the Wavertree Playground from June 21–25. We notice that prizes to the value of 450*l*. are offered for the best managed farms in four classes, duly specified in the report, the competition being confined to tenant farmers resident in Lancashire and Cheshire. The society is also offering a gold medal for the best agricultural motor. A pleasing increase in the number of samples analysed in the society's laboratory is recorded, the number for the last twelve months being 475, as against 410 in 1908. The work at the Woburn Experimental Farm and Pot-culture Station has progressed well. The field experiments have included an extensive series on the relative value of the new nitrogenous manures, calcium cyanamide and calcium nitrate, in comparison with ammonium sulphate and sodium nitrate; also a further trial has been given to "nitro-bacterine" and other methods for inoculating leguminous and other crops, and the experiments with magnesia on different field crops have been carried a stage further. Satisfactory work is reported also in the botanical and zoological departments.

An article upon "The Danger of the Comet," contributed to the December number of *Pearson's Magazine* by Mr. E. C. Andrews, contains some interesting particulars—popularly expressed—relating to Halley's and other comets, and an imaginative description of the consequences of a collision between the earth and a comet. As nothing is definitely known about the size of the meteorites which probably form a comet's head, the result of the earth passing through the head is problematical. If the head is merely a condensed swarm of cosmic dust particles, there would be a fine shower of shooting-stars, but if the meteorites in it weigh tons instead of grains or ounces, the consequences of a collision with it would, of course, be serious. The tail of a comet is, however, so extremely attenuated in its nature that even if it consists of poisonous gases our atmosphere is not likely to be appreciably affected by it. To describe the tail, as Mr. Andrews does, as a "dense stream of fiery fragments" is, to say the least, misleading. No comet has a mass which is as much as the hundred-thousandth part of the earth's mass; in other words, the total mass of any comet is less than that of a ball of iron 150 miles in diameter. The fall of a comet into the sun would, therefore, not produce more heat than the sun radiates in eight or nine hours. As Prof. C. A. Young remarked, when referring to the possibility of this event, "there might, and very likely would, be a flash of some kind at the solar surface as the shower of cometary particles struck it, but probably nothing that the astronomers would not take delight in watching." It is desirable to remember facts like these when speculating upon the subject of danger from comets.

The report of the committee of the Warrington Museum for the year ending at Midsummer last records the additions to the collection during the year. The curator ought to be aware that *Vespertilio auritus* is not the proper designation for the long-eared bat.

In a paper published in the *Boletin de la Instrucción Pública*, Buenos Aires, Mr. R. Sinet gives an illustrated summary of Dr. Ameghino's views with regard to the pedigree of the human species, especially dwelling on the supposed evidence of the evolution having taken place from marsupial-like ancestors in South America itself.

In vol. xl., part i., of the *Comptes rendus de la Société Impériale des Naturalistes de St. Pétersbourg*, Mr. G. Nilus describes two polyzoans, *Loxosoma murmanica* and *L. brumpti*, collected in Kola Fjord, on the Murman coast, where they occurred in great profusion, accompanied by other polyzoans and the gephyrean *Phasiolion spitzbergense*.

The first two articles in the January-June issue of the *Sitzungsberichte und Abhandlungen* of the Dresden Institute are devoted to subjects connected with Darwinism and Darwin, Dr. E. Kalkowsky dealing in the former with the geological foundation of the doctrine of evolution, while in the latter Prof. O. Drude discourses on the theory of the origin of species, and especially the publication of the famous volume bearing that title, as a land-mark in the life of Darwin.

According to a paper by Mr. L. B. Taylor, published in the October number of the Journal of the South African Ornithologists' Union, Verreaux's eagle (*Aquila verreauxi*) constructs its nest in Cape Colony entirely of the green boughs of a rough bush, which must be very difficult to break off. The only other instance of the use of similar material for nest-making occurs in the case of the African *A. wahlbergi*, where it is used as lining. *A. verreauxi* preys, to a great extent, on hyraxes, numerous remains of which were found in the nest examined by Mr. Taylor, but also hunts and kills a certain number of klipspringers.

The latest issue (vol. vi., anno 3) of *Rivista di Scienza* contains three articles on geological subjects, Prof. L. de Marchi dealing with mountain-formation, Prof. F. E. Mess contributing the second instalment of an interesting article on modern theories of volcanic action, and Messrs. P. Enriques and M. Gortani discussing the succession of geological periods. The last-named article is of a somewhat remarkable character, as the authors deny the existence of any such definite periods. They do not, however, propose to abolish the generally accepted geological classification, which they consider necessary for the convenience of study, but content themselves with pointing out its purely artificial character.

The important subject of the working of teak forests comes in for discussion in the *Indian Forester* (October). Mr. J. F. Troup, the imperial superintendent of forest working-plans, recommends measures for improvement fellings in the Burma forests associated with burning of undergrowth to help natural reproduction and produce even-aged crops. With reference to the mixed teak forests in the Central Provinces, where the system is coppice with standard, Mr. C. M. McCrie points out that information is wanting as to the longevity of coppiced stools and coppice shoots, also as to the fertility of seed produced by the latter.

For many years coffee plantations in Central America have suffered from the attacks of a parasitic fungus which is said to be almost as dangerous as its better known eastern congener, *Hemileia vastatrix*. Little information has been available concerning the life-history of the fungus except the production of a conidial stage on diseased leaves, shoots, and fruits, to which Cooke gave the name *Stilbum flavidum*. Mr. G. Massee now records in the *Kew Bulletin* (No. 8) that he has obtained an ascus-forming (Nectria) stage, which transfers the fungus to the genus Sphærostilbe. Unlike the conidia, the ascospores readily produce infection in healthy leaves, leading to the formation of the customary white spots and conidiophores.

A study of the phytoplankton gathered in the North Atlantic Ocean affords a great deal of variation, as will be realised from the results published by Mr. W. Stüwe in Engler's *Botanische Jahrbücher* (vol. xliii., part iv.). From Dover to Brest the plankton is coastal, and consists almost entirely of diatoms, with a preponderance of species of Coscinodiscus and Biddulphia. Thence to the Azores species of Ceratium abound in the deeper waters, but in the neighbourhood of the Canaries the increase of Bacillariaceæ betokens an influx of coastal forms. Around the Cape Verde Islands Trichodesmium is dominant in the equatorial currents. Another type of vegetation is met with in the Sargasso Sea, in which species of Ceratium, notably *Ceratium tripos protuberans*, are common. With regard to vertical distribution, in the colder waters the Bacillariaceæ predominate at the surface, while the Peridineæ occur in the next zone; in the warm seas the Peridineæ lie at the surface, and the diatoms are found below.

The results of manurial experiments on the sugar-cane, carried out at the Experiment Station of the Hawaiian Sugar-planters' Association, have just been issued (Bulletin No. 29). The results could not be correlated with the chemical composition of the soil as determined by the ordinary methods of analysis or by the aspartic acid method first used in Hawaii, and the author concludes that the profit resulting from the application of manures will depend largely upon other factors than the chemical composition of the soil. The greatest loss from the use of improper mixtures of fertilisers was found to occur in acid soils.

We learn from the *Journal of Agriculture of South Australia* that the Irish potato blight (caused by the fungus *Phytophthora infestans*) has made its appearance in several of the Australian States. It does not appear that the disease is yet very widespread, and by mapping out the affected areas and adopting suitable precautions within those areas it should be possible to prevent great damage being done. A well-illustrated account of the disease is given, so that the practical man may readily recognise it, and methods of treatment are fully described. Spraying with Bordeaux mixture is a well-recognised preventive measure, and is discussed at some length.

A summary has recently been issued from the New Jersey Agricultural Experiment Station of the investigations carried out by Messrs. Voorhees and Lipman on various nitrogenous manures. Out of a hundred parts of nitrogen supplied as nitrate of soda, sixty-two parts were recovered in the crop over a period of ten years, and in the case of ammonium sulphate forty-three parts were recovered; these results agree almost exactly with those obtained by Wagner at Darmstadt. The relative availability of the various fertilisers tested was:—

Sodium nitrate	100
Ammonium sulphate	69·7
Dried blood	64·4
Solid manure (fresh)	35·9
Solid and liquid manure (fresh)	53·0
Solid and liquid manure (leached)	43·1
Solid manure (leached)	38·9

The fundamental importance of irrigation and of methods of dry-farming in South Africa is well brought out in a series of articles in recent issues of the *Agricultural Journal of the Cape of Good Hope*. Throughout considerable areas of South Africa the rainfall is either insufficient or is too irregularly distributed for the best crop returns to be obtained, and the chief problem in arable farming becomes the provision of proper water supply. Recourse may be had either to irrigation or to "dry farming," the former being more generally applicable than the latter. A delegate was sent to the National Irrigation Congress at Albuquerqu, New Mexico, U.S.A., and his report contains many suggestions likely to be of value in evolving methods suited to South Africa. There is also a report on the possibilities of irrigation in Bechuanaland. By way of encouraging dry farming, the De Beers Company is offering at the next Bloemfontein show a prize of 20*l.* for the best exhibit of maize grown on "dry lands" without irrigation.

In *Man* for November Mr. W. G. Aston raises the question of the origin of sexual antipathy among near relations.

Contesting the views of Messrs. Ellis and Crawley, he regards it as mainly based on a recognition by even savage tribes of the physical dangers of interbreeding. He lays stress on the dogma of Dr. Tylor that "exogamy was an early method of political self-preservation" in widening the influence of the clan by foreign alliances. Nothing is more fatal to a clan than consanguineous marriage, "and few things are more vital to the welfare of a family, a tribe, or a nation than the right ordering of the sexual relations."

IN the September number of *Spolia Zeylanica*, issued by the Colombo Museum, Ceylon, Mr. P. Arunachalam describes the ancient bronzes in the collection, and Mr. D. Wickremasimghe contributes notes on the inscriptions attached to them. The antiquity of the specimens is not very great. King Sigiri Kasypa rendered, we are told, "a lasting service to the chronological history of Ceylon by murdering his father in the fifth century A.D.; but for this signal act of parricide Ceylon dates would be in a greater state of confusion than they are," the date of this event separating the Mahawansa from the so-called Sulawansa period, which terminated in 1815 A.D. All the ancient bronzes in Ceylon belong to the period corresponding to the Middle Ages of Europe. The catalogue is well illustrated with photographs of the more notable specimens, and is of interest as facilitating the comparison of Sinhalese with Hindu art.

THE monthly review of cartography in *Petermann's Mitteilungen* (p. 281) contains articles by Dr. Max Gasser and Herr Moedebeck, president of the International Commission for "Luftschifferkarten," on maps for use on balloons and flying machines. The arrangement recommended is a general map on a scale of 1/1,000,000, with a smaller 1/200,000-map for the details of routes. The requirements of aërial navigation are dealt with in considerable detail, and a system of conventional signs and colours is proposed. It is suggested that the larger scale map should show parallels at intervals of ten minutes and meridians at intervals of twenty minutes, in accordance with the methods for astronomical determination of position worked out by Dr. Marcuses. Specimen maps accompany the papers.

IN *Symons's Meteorological Magazine* for November Dr. H. R. Mill gives a preliminary account of the remarkable rainfall of October 26–28 in the south of England. On the morning of October 26 the centre of a deep barometric depression lay to the south of Ireland, and moved slowly to the south-eastward; on October 28 a change of direction took place, the centre moving north-easterly, the effect being to enclose the south of England between the S.E. and N.E. paths of the depression. A list of the records is given for places where more than 2·5 inches of rain fell in one day, and more than 4 inches in three consecutive days. Both these conditions obtained in parts of Kent, Sussex, and the Isle of Wight. Among the heaviest falls during the three days, we note 6 inches at Ramsgate and 5·27 inches at Brighton; so far as available records show, no previous daily fall of 3 inches had been observed within twenty miles of Brighton, where 3·60 inches fell on October 26, or within forty miles of Broadstairs, where 3·14 inches fell on October 28. The month over the country as a whole was by no means so wet as October, 1903.

THE *Journal de Physique* for November contains a description of an electromagnetic compass suitable for use on board ironclads, which was described before the Société française de Physique more than a year ago by the inventor, M. Louis Dunoyer, and has now been tested on board one of the French cruisers. The apparatus consists of a solenoid wound with two wires in parallel, which can be rotated at a constant speed about a vertical axis to which its own axis is perpendicular. The ends of each of the two wires are connected to a two-part commutator on the axis of rotation, and the two pairs of brushes bearing on the commutators are set at right angles to each other. From the brushes wires lead to the coils of two moving coil galvanometers. The coils move about horizontal axes at right angles to each other, and mirrors attached to them produce images of two lines of light on a horizontal ground-glass screen. As the solenoid rotates the mean currents through the galvanometer coils are proportional to the sine and cosine of the angle between the axis of the ship and the horizontal component of the earth's magnetic field, and the line joining the crossing point of the two images to the centre of the screen gives the direction and magnitude of that component. The apparatus allows of ready compensation for both permanent and temporary magnetism of the ship. As the ship is "swung" the crossing point of the lines of light describes on the glass screen an ellipse, the axis major of which will, in general, be inclined to the direction of motion of both the galvanometer coils. By rotating the solenoid with respect to the commutators, the axis may be made to coincide with one of these directions. It is then only necessary to add resistance to the circuit of the coil which gives the larger deflection to reduce the ellipse to a circle, which would be the figure obtained if the earth's magnetic field were undisturbed by the vessel. The method is evidently very flexible, and admits of the observations being taken in the cabin while the rotating solenoid is placed on deck.

A PAPER on concrete pile foundations was read by Mr. Alex. Melville on November 23 before the Institution of Engineers and Shipbuilders in Scotland. Special reference was made to the Simplex method, a system which has been specified by the Admiralty for the naval base at Rosyth. This system is the invention of Mr. Frank Shuman, of Philadelphia, who took out his first patents in 1903. The essential principle lies in the driving of a tube or forme constructed of lap-welded steel, the lower end of which is closed by a loose point or by a pair of hinged jaws. These jaws open when the tube is being pulled up and permit concrete to be passed through, filling up the space left by the tube simultaneously with its withdrawal. The jaws are, as it were, cut out of a cylinder of exactly the same section as the sleeve, and so lie close against the sides of the hole left by the sleeve as the forme is withdrawn, thus offering no obstruction to the free passage of the concrete. A driving cap is attached to the top of the forme when the pile-driver is at work. On completion of driving the cap is removed, and concrete is filled into the forme to a height of several feet above the level of the finished head of the pile in order to allow for sinking as the forme is withdrawn, an operation performed by means of tackle connected to the pile-driver. Such piles can be inserted to any depth, and can be put in as close as 3 feet from centre to centre; reinforced piles on this system may also be executed. The method has many advantages, and has been very successfully applied in this and other countries.

Engineering for November 26 has an interesting leading article on the encouragement of aviation. Although there are some small signs of our waking up, everybody must deplore our backwardness in taking a lively and efficient interest in the new movement. It cannot be said, in regard to aviation, that public or national bodies have interfered with onerous legislation such as has retarded other budding industries. The movement has received but little encouragement in the way of State-aided experimental work; plenty of private pioneer work has been done—indeed, we were among the first to take seriously to aëronautics—yet we are woefully behind our neighbours. Extremely rapid progress has been made recently in other countries in heavier-than-air machines, and it seems clear that we should actively encourage the development of that branch of the science which appears of the greatest promise. Two methods have been adopted on the other side of the Atlantic which we might do worse than imitate. One is a national competition promoted by the United States War Department; the other is the method adopted by Dr. Graham Bell, who collected around him a number of ardent workers, who banded themselves together with the object of producing several successful machines. These men were all well acquainted with the principles underlying the art, and their collective wisdom has been well proven in the results achieved. Our own few earnest workers worry along independently, until financial stress often directs their attention to other matters. Continuing, our contemporary thinks that the movement of aviation is not in the right hands. Anyone who attends the meetings of the two best known societies connected with aëronautics must know that the discussions are not at all on a high level, and compare very unfavourably with those at, say, the Institution of Civil Engineers or the Institution of Mechanical Engineers. It is admitted that sport is quite a legitimate opening for aviation, as it has been for yachting and motoring; but, as has happened in these latter sports, the flying machines now built merely to win races will probably give place to machines of a more serviceable type when the movement has become leavened with the ideas of engineers and the results of scientific studies.

Evidence of the interest that is taken in the isomeric change of optically active compounds is afforded by two papers by Mr. H. Wren in the October number of the Chemical Society's Journal. The substance selected for examination was *l*-benzoin, $C_6H_5.CHOH.CO.C_6H_5$, a compound which contains an asymmetric carbon atom, but would lose its optical activity if converted into the isomeric "enol," $C_6H_5.C(OH):C(OH).C_6H_5$, and might therefore be expected to racemise with great readiness, at least in presence of an alkaline catalyst. The experiments carried out by the author showed that *l*-benzoin retained its activity in the crystalline state during three months, and that its solution in acetone was unchanged at the end of eight days. The addition of a small quantity of sodium ethoxide to its alcoholic solution was, however, sufficient to destroy its optical activity in a single day. The methyl ether, $C_6H_5.CH(OCH_3).CO.C_6H_5$, lost its optical activity completely in five minutes when dissolved in alcoholic potash of N/9 strength, and a progressive racemisation by dilute sodium ethoxide was completed in the course of three hours. Complete racemisation took place on attempting to prepare the ethyl ether by means of alcohol and hydrogen chloride, and a partial loss of activity took place when silver oxide and ethyl iodide were used. The oxime $C_6H_5.CH(OH).C(:NOH).C_6H_5$, and carbanilide

$$C_6H_5.CH(O.CO.NH.C_6H_5).CO.C_6H_5,$$

were found to be optically active, but the former suffered a partial loss of activity on acetylation, and the latter was completely racemised by heating above its melting point during four hours at 140°, contact with the glass being shown to be an important factor in promoting the change. A racemic product was also obtained on condensing *l*-benzoin with aniline. The changes here recorded are very similar to those that have been observed amongst the derivatives of camphor, but differ from them in that the inversion of the one asymmetric carbon atom causes a total loss of optical activity.

Dr. Maximilian Toch, of New York City, in his address as chairman of the American Society of Chemical Industry, dealt with the influence of chemistry on civilisation. The address is published in the issue of *Science* for November 19. In the course of his remarks, Dr. Toch said:—Chemistry needs no sponsor, but its effect on civilisation has been more marked than that of any other science. True, it has reached out and taken electricity and physics as aids, but, withal, engineering made but little progress until steel and cement—two chemical products—were cheapened, simplified, and made universal. Medicine has claimed great honours, but the masterful work done in coal-tar chemistry, in the production and discovery of synthetic drugs, the discovery of anæsthetics, the marvellous work done in the metabolism of matter, the excellent analytical schemes for the waste matter of the tissues, are all due to the researches of chemistry, and their civilising influence is greatly felt. The engineer may boast of his skill, but he has done nothing greater than the pyramids, nor finer than the temples of Greece and Egypt. The monuments he has wrought in steel were given to him by the ability of the chemist to control carbon in iron, and the economic principle involved in the production of steel supplies work, puts money into circulation, and keeps the wheels turning. For a science so young its civilising influence is enormous, and there is no doubt that the rapid progress which chemistry made in the nineteenth century will be outstripped in the twentieth, for the control of our foodstuffs, the application of the raw materials in the earth, and the refining of metals, create positions, give progress to a country, and help largely in the establishment of chemistry as a profession.

The Geological Society has published a catalogue of the geological literature added to the society's library during the year ended December 31, 1908. The catalogue has been compiled by the assistant-librarian and edited by the assistant-secretary, and its price is 2*s*.

Messrs. Flatters and Garnett, Ltd., 32 Dover Street, Manchester, have just issued a new classified catalogue of lantern-slides illustrating various subjects of biology, geology, astronomy, physiography, textile fibres, machinery, &c. The slides are from drawings, photographs of specimens, and photomicrographs, and most of them are not to be found in other catalogues. For the illustration of lectures or lessons in biological and other subjects many of the slides should prove very valuable.

OUR ASTRONOMICAL COLUMN.

Discovery of a New Comet, 1909*e*.—A telegram from the Kiel Centralstelle announces the discovery of a comet by Prof. Daniel, at Princeton, on December 6. Its position at 9h. 23·9m. (Princeton M.T.) was

$$R.A. = 6h.\ 16m.\ 32s.,\ dec. = 33°\ 50'\ N.,$$

and its magnitude was estimated as 11·0. This position lies at about the centre of the triangle formed by θ and κ Aurigæ and θ Geminorum. The comet is said to be moving slowly in a northerly direction.

Halley's Comet.—According to the ephemeris, Halley's comet is now approaching the sun at a rate of about 1,230,000 miles per day, whilst its distance from the earth is decreasing daily by some 460,000 miles; its distance from the earth on December 11, at 9 p.m., will be about 128·5 million miles.

Observations made at the Solar Physics Observatory, South Kensington, with the 36-inch reflector, show that the comet is a nebulous object, easily recognisable, and having no visible nucleus; exposures of five to ten minutes give a distinct image, and show how rapidly the object is moving in relation to the surrounding stars.

With a 3-inch Dallmeyer portrait lens, Mr. Longbottom, Chester, succeeded, on November 21, in photographing an excellent image of the comet, on an Ilford plate, in thirty minutes.

Absorption of Light in Space.—In this column for February 25 (vol. lxxix., p. 499) we directed attention to Prof. Kapteyn's researches on the absorption of light during its passage through interstellar space, in which he found a value corresponding to an absorption of 0·016 of a magnitude in a distance of thirty-three light-years.

Another paper dealing with this subject he now publishes in vol. xxx., No. 4, of the *Astrophysical Journal*, and as No. 42 of the "Contributions from the Mount Wilson Solar Observatory." The criterion he adopts is that such absorption would manifest itself, *ceteris paribus*, by the more distant stars being redder than the nearer ones. The subject is too complicated to discuss here, but, by comparing the photographic and visual magnitudes of stars of which the spectral types are known, from Misses Maury's and Cannon's classifications, and for which measures of distance are available, he succeeds in showing that such absorption probably does exist. The results indicate that for the photographic rays the loss per 32·6 light-years is 0·00945, while for the visual rays it is 0·00465, magnitude; the final value for *d* (increase in redness per 32·6 light-years) is 0·0066±0·0031 magnitude. Apparently there is no reason for assuming the absorption to be different in galactic and extra-galactic stars.

Incidentally, Prof. Kapteyn finds that for stars of the same spectral class, the ratio between the brightness of the violet radiations and that of the visual rays changes largely with the apparent magnitude. This, however, is probably a photographic, and not a cosmical, phenomenon.

Prof. Kapteyn's result proves abundantly that such large values, for the absorption, as are implied by the results recently brought out by certain investigators must be illusory.

Copernicus Anticipated.—No. 21 of the *Revue générale des Sciences* (November 15, p. 866) contains an interesting article, by M. Pierre Duhem, giving an account of the life and works of Nicole Oresme, who became Bishop of Lisieux in 1377, and died at that place in 1382. Oresme translated, with commentaries, the four books of Aristotle, but the translation was never printed, although there are several manuscript copies; it is on one of these that M. Duhem bases his note. In this work, Oresme, commenting on Aristotle's contentions for an unmovable, central earth, gives numerous reasons and arguments against such an hypothesis, and clearly shows that, in his opinion, it was entirely wrong. In concluding his note, M. Duhem suggests that, not only was Oresme the precursor of Copernicus, but he may have been, also, the inspirer.

Star Almanac and Calendar for 1910.—From Messrs. King, Sell and Olding we have received copies of "The Star Almanac for 1910," "The Star Calendar for 1910," and "The Stars from Year to Year." These works, for 1909, were reviewed in our columns for December 3, 1908, and maintain the favourable opinions then expressed concerning them. The prices are 3*d*., 1*s*., and 1*s*., respectively.

MAGNETIC EXPEDITIONS.

Of the many successfully conducted land expeditions sent out by the Department of Terrestrial Magnetism of the Carnegie Institution of Washington since its establishment in 1904, news has just been received of the successful completion of two of the most important and interesting ones. Mr. D. C. Sowers headed an expedition which started out from Peking, China, on January 30 of this year, passing through China and Chinese Turkestan, reaching Kashgar on August 2, and then crossing the Himalayan range and arriving at Leh, India, at the end of September. Magnetic observations and other geographical data were obtained along the entire route traversed. Mr. Sowers's chief assistant was Prof. Fuson, formerly professor of history and geography at the Christian College, Fuson, China.

Mr. C. C. Stewart started out from Washington last July to take charge of a canoeing magnetic exploring expedition in British North America. After reaching Lake Abitibi the party next proceeded to Moose Factory, then crossed James Bay to Rupert House, then up the Rupert River, and coming out at Roberval, Lake St. John, the middle of October.

News has also been received of the successful progress of the land magnetic surveys in Africa under the charge of Profs. Beattie and Morrison, research associates of the Carnegie Institution, and of the magnetic work in charge of Mr. J. C. Pearson in Persia, Asia Minor, and southern Asiatic Russia.

With the resumption of the ocean magnetic work by the *Carnegie*, the director of the department, Dr. Bauer, estimates that at the present rate of progress it will be possible in another five years to construct accurate magnetic charts of declination, dip, and force, as based on freshly acquired data, for the region of the earth 60° N. to 60° S.

The department is also cooperating with polar expeditions so as to secure information in regions which cannot be entered by the *Carnegie*, this vessel not having been built for going into the ice. Thus instruments were loaned and instructions drawn up for Mr. Jackson, of the Canadian Meteorological Office, who was detailed for duty on the Canadian exploring steamer *Arctic* (formerly the *Gauss*), in command of Captain Bernier, the vessel having recently returned to Quebec. Mr. Jackson has informed Dr. Bauer that he has secured a series of magnetic, atmospheric electric, tidal and meteorological observations at various points in the Arctic regions.

So also Dr. C. C. Craft, magnetic observer of the department, was assigned to Commander Peary's auxiliary steamer, the *Eric*, a year ago, and obtained magnetic data at a number of points in Labrador, Baffin Land, and Greenland.

During the past summer Mr. E. Kidson, formerly assistant at the Christchurch Magnetic Observatory, completed a magnetic survey of the interior of Newfoundland, and in the early part of the year an expedition, in charge of Mr. C. Sligh, made magnetic observations along the coasts and in the interior of Central America.

ETHNOGRAPHY IN THE PHILIPPINE ISLANDS.

The Government Bureau of Science of the Philippine Islands is actively prosecuting inquiries into the physical anthropology and ethnography of the archipelago. The fourth part of the fourth volume of its Proceedings contains two papers of more than ordinary importance.

Mr. R. B. Bean contributes an elaborate article on the littoral population of Luzon and the adjacent islands, based on measurements of students at Manila. The view generally accepted is that of M. L. J. Montano ("Rapport a M. le Ministre de l'Instruction publique sur une Mission aux Îles Philippines et en Malaisie," Paris, 1879–81), who classes the inhabitants of the mountainous regions of the interior as Negritos; those of the fertile parts of the interior as Indonesian; those of the coast lands as Malay. In addition to these there is a considerable Spanish element, and, since the last conquest of the archipelago, American and negro mestizos or half-castes are springing up in every part of the islands, thus presenting in a very mixed population a series of most interesting problems for the physical anthropologist. Mr. Bean, from his recent inquiries, classifies the coast population into Modified Iberian, Australoid, and Primitive, with several intermediate types. The Modified Iberians correspond to the Mediterranean race of Sergi; the Australoids are below the medium height, with narrow heads, broad noses and faces; the Primitives resemble the latter, but have a cephalic index ten in excess of the Iberian. The Australoid and Primitive types are probably the original elements in the population, the other types representing modifications caused by the introduction of Europeans and Chinese, recent and remote. The result is an improvement in all the physical measurements, which, with increasing European and Chinese immigration, will probably advance, and be accompanied by an increase of bodily and mental vigour, a process facilitated by improved nutrition and in hygiene by the reduction of noxious parasitic life.

The second paper devoted to pure ethnography is an account, by Fr. Juan Villaverde, of the Quiangan Ifugao tribes. They are of Negrito affinities, and present a remarkable combination of an advanced culture with savagery. They live by agriculture, cultivating rice in the hilly tracts by an elaborate system of terrace farming, by which they utilise the supplies of spring water which they consider necessary to the growth of this crop. They have neither king nor rulers, but are divided into two distinct grades, the nobles exercising considerable authority over the plebeians. A man can rise to the higher from the lower class by the exercise of profuse hospitality, which is provided by a series of elaborate feasts. They respect the aged, who act the part of priests in their idolatrous rites, and generally hold women in high estimation. They divorce their wives continually, each of the pair readily finding a fresh partner. Their worship is chiefly that of the moon and other heavenly bodies, and they practise divination to relieve the fears of the spirit world which always beset them. They lend and borrow on exorbitant interest, and sons are responsible for the debts of their parents. Combined with this fairly advanced culture they are grossly addicted to drunkenness, and the absence of any controlling authority leads to constant blood feuds, every murder being followed by inexorable vengeance extending, not only to the offender, but embracing his nearest relatives. This is accompanied by the custom of head-hunting, in which even women, though ordinarily respected, and children are not spared, the heads of the victims being brought home in triumph, and the fronts of the houses decorated with the captured heads.

Ifugaos with wooden shovels, Banaue.

THE DEVELOPMENT OF EVOLUTIONARY IDEAS.

THE annual Herbert Spencer lecture was delivered at Oxford on December 2 by the Linacre professor, Dr. G. C. Bourne. In the course of a brief historical sketch, the lecturer pointed out that evolutionary ideas were widely prevalent at the end of the eighteenth century, though, after being apparently routed by Cuvier, the doctrine remained for many years in abeyance. Herbert Spencer was a pioneer in the evolutionary revival. Not an original investigator in zoology or botany, he was yet a very earnest student of biological subjects. Evolution, in Spencer's view, was a cosmic process, consisting essentially in the passage of the homogeneous into the heterogeneous. Confronted with the difficulty of the transition from the non-living to the living, Spencer framed the theory of "physiological units" with their mutual interactions. This proved to be a fertile idea, and was adopted in one form or another by many subsequent investigators. In phylogeny there is a real advance from the homogeneous to the heterogeneous; in ontogeny, however, there are obvious difficulties in the way of this interpretation. These difficulties Herbert Spencer tried to meet by assuming for his units "polarities" of differing values, and a power of undergoing modification when subject to the influence of each other and of the environment. Hence a true epigenesis took place, and in this way he thought it possible to account for both inheritance and variation. Acquired characters, he held, *must* be inherited; and on this basis he reared the fabric of the "synthetic philosophy."

Against the system thus outlined, two crushing blows were delivered by Weismann. The first was his insistence on the fact that there is no clear evidence of the inheritance of acquired characters; the second was the demonstration that the germ-plasm in ontogeny is from the first a structure of very great complexity. The germ, it was found, must have historical properties, and the embryological history of the individual is really a genealogy.

The bearing of recent experiments in the "mechanics of development" upon the views of Spencer and Weismann respectively was very carefully and lucidly explained by Prof. Bourne, who showed that the pre-existence of certain materials in the germ, and their subsequent sorting out in the course of ontogeny, facts which could no longer be denied, were entirely adverse to the Spencerian conception. On the other hand, the view of Weismann, though in some particulars erroneous, received in the main a strong confirmation from experiments by the followers of Mendel. Prof. Bourne concluded his discourse by urging that biological studies were no mere plaything, but of the highest importance for dealing with human affairs. An essential link was now broken in the chain of the synthetic philosophy, and it behoved those concerned in such matters to inquire whether our sociological methods were right, and whether certain schemes of social improvement, founded on the biological principles of fifty years ago, should not be re-considered in the light of those of the present day.

RESEARCHES IN RADIO-TELEGRAPHY.[1]

II.

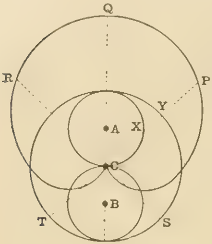

Fig. 13.

In a previous discourse explanations were given of the property of a closed or partly closed antenna of radiating more in some directions than others, and the action of Marconi's bent antenna was described. Two other inventors, Messrs. Bellini and Tosi, have taken advantage of this fact to construct antennæ of a very interesting character. They erect an antenna consisting of two wires, each bent into a triangular form, the top ends nearly meeting, the planes of these triangles being at right angles to one another, and both of them vertical. The nearly closed antenna circuits are then inductively coupled with a condenser circuit, which is capable of being swivelled round in various directions. If the said condenser circuit is placed in such a position as to be coupled with one of the triangular antennæ it will cause the maximum radiation to take place in the plane of that antenna, but none at all at right angles to it. If it is coupled with the other antenna it will cause radiation to take place to a maximum degree in the plane of that second antenna. If, however, the oscillatory circuit is placed in an intermediate position, so as to act inductively upon both the nearly closed triangular antennæ, then it can be shown, both mathematically and experimentally, that the radiation of the combined system is a maximum in the direction of the plane of the oscillatory circuit which is coupled with the antenna. Hence, with such a combined antenna, we have it in our power to create radiation most strongly in one direction, although not entirely suppressed in all other directions. By combining together, however, a single vertical antenna with two nearly closed circuit antennæ at right angles to one another, Messrs. Bellini and Tosi have constructed a complex antenna which has the property of producing radiation almost entirely limited to one-half the circumjacent space (Fig. 13). It therefore corresponds to a certain extent in effect to the optical apparatus of a lighthouse, with catoptric or dioptric apparatus, which projects the light from the lamp largely in one direction. It is not yet possible to make with electric radiation of long wave-length that which corresponds precisely with a beam of light wholly concentrated along a certain cone or cylinder, but it is possible, by the use of a complex antenna as described, greatly to limit the diffusion of the radiation. Since radiating and absorbing power go hand in hand, it is obvious that such a directive antenna also enables the position of a sending station to be located. Messrs. Bellini and Tosi have accordingly applied their methods in the construction of a *radiogoniometer* and receiving antenna, by means of which they can locate the direction of the sending station without moving the antenna, but merely by turning round a secondary circuit into a position in which the maximum sound is heard in a telephone connected with the receiver. By the kindness of Captain Tosi I am able to exhibit to you their ingenious apparatus (Fig. 14).

The space occupied by such closed antennæ has hitherto prevented their employment on ships. There is still, therefore, an opening for the invention of apparatus capable of being used on board ship which will enable one ship to locate, within narrow limits, the direction of another ship sending signals to it, and therefore of ascertaining immediately the direction from which some call for help is proceeding.

We must pass on to notice, in the next place, some improvements in oscillation detectors and means of testing them. As already explained, the æther waves sent out by the transmitting antenna fall on the receiving antenna and create in it, or some other circuit connected to it, very feeble oscillations. These oscillations being very feeble, alternating currents of high frequency cannot directly affect either an ordinary telegraphic instrument or a telephone, but we have to interpose a device of some kind called an oscillation detector, which is affected by oscillations in such a manner that it undergoes some change, which in turn enables it to create, increase, or diminish a local current produced by a local battery, and so affect a telephone or telegraphic relay. One kind of change the oscillations can produce in certain devices is a change in their electric resistance, which in turn is caused to increase or diminish a current through a telephone or telegraphic relay generated by a local battery. To this type belong the well-known coherers of Branly, Lodge, and Marconi, which require tapping or rotating to bring them back continually to a condition of sensitiveness.

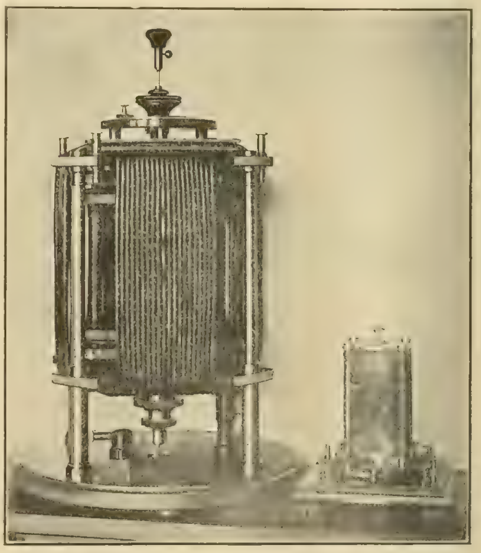

Fig. 14.—Bellini and Tosi's Radiogoniometers for Directive Radiotelegraphy.

Coherers, however, have been devised which require no tapping. Thus it has been found by Mr. L. H. Walter that if a short length of very fine tantalum wire is dipped into mercury there is a very imperfect contact between the mercury and tantalum for low electromotive forces. This may perhaps arise from the fact that tantalum, like iron, is not wetted by mercury. If, however, feeble electric oscillations act between the mercury and tantalum, the contact is improved whilst they last. If, then, the terminals of a circuit containing a telephone in series with a shunted voltaic cell are connected to the mercury and tantalum respectively, and if damped or intermittent trains of electric waves fall on an antenna and excite oscillations which are allowed to act on the mercury-tantalum junction, then at each train the resistance of the contact falls, the local cell sends current through the telephone and produces a short sound, and if the trains come frequently enough this sound is repeated and will be heard as a continuous noise in the telephone (Fig. 15). This sound can be cut up into dot and dash signals by a key in the sending instrument. If the transmitter is sending persistent oscillations, then some form of interrupter has to be inserted in the receiving circuit to enable us to receive a continuous sound in the telephone, which can be resolved into Morse dot and dash signals by the key in the transmitter. The operator usually wears on his head a double telephone, and listens to these long and short sounds in the telephone, and writes down each letter or word as he hears it.

---

[1] From a discourse delivered at the Royal Institution, on Friday, June 4 By Prof. J. A. Fleming, F.R.S. Continued from p. 144.

The reception of signals in modern radio-telegraphy is most usually effected by ear by means of some type of oscillation detector capable of actuating a telephone. It is important, then, to notice that, to obtain the highest sensitiveness when using the telephonic method of reception, the spark frequency or number of oscillation trains or the number of interruptions of the persistent train per second must take place at such a rate that it agrees with the natural time period of the diaphragm of the telephone used. An ordinary telephone receiver is most sensitive, according to the researches of Lord Rayleigh and M. Wien, for some frequency lying between 500 and 1000. Thus Lord Rayleigh (see *Phil. Mag.*, vol. xxxviii., 1894, p. 285) measured the alternating current in microamperes required to produce the least audible sound in a telephone receiver of 70 ohms resistance at various frequencies, and found values as follows:—

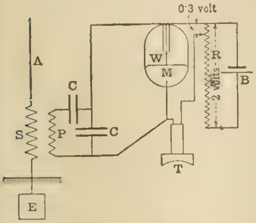

FIG. 15.—Walter's Tantalum Detector.

TABLE II.

Frequency...	128	192	256	307	320	384	512	640	768
Least audible current in microamperes	28	2·5	0·83	0·49	0·32	0·15	0·07	0·04	0·1

M. Wien found for a Siemens telephone somewhat different results, viz.:—

Frequency...	64	128	256	512	720	1927	1500
Least audible current in microamperes ...	12	1·5	0·13	0·027	0·008	0·013	0·024

Both, however, agree in showing a maximum sensitiveness for currents of a frequency between 600 and 700. This is due to the fact that the frequency of the actuating current then agrees with the natural frequency of the ordinary telephone diaphragm. Hence alternators for large-power radio-telegraphic stations are now designed to give currents with a frequency of about 300 or 600 alternations per second, so that, when producing discharges of a condenser, the number of sparks per second may be at least 600, and fulfil the conditions for giving maximum sound in the telephone of the receiver per microampere.

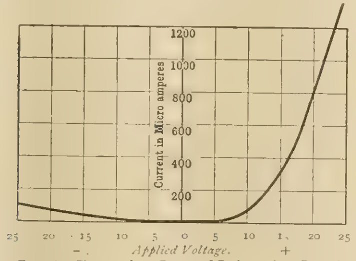

FIG. 16.—Characteristic Curves of Carborundum Crystal.

Another class of oscillation detector recently discovered comprises the crystal detectors, which depend on the possession by certain crystals of the curious property of acting as an electrical valve, or having greater conductivity in one direction than the other, and also on not obeying Ohm's law as conductors. It was discovered by General Dunwoody, of the United States Army, in 1906, that a mass of carborundum, which is a crystalline carbide of silicon formed in electric furnaces, can act as a detector of electric oscillations if inserted in the circuit of an antenna, the crystal mass being held strongly pressed between two spring clips, which are also connected by a shunted voltaic cell in series with a telephone. When feeble oscillations are set up in the antenna, a sound is heard in the telephone.

This property of carborundum has been carefully investigated by Prof. G. W. Pierce, of Harvard, and he showed that a single crystal of carborundum has remarkable unilateral conductivity for certain voltages when held with a certain contact pressure between metallic clips. Thus for a crystal held with a pressure of 1 kilogram, and subjected to an electromotive force of 30 volts, the conductivity in one direction through the crystal was 4000 greater than in the opposite direction (Fig. 16). The result of these experiments was also to show that the current voltage curve or characteristic curve of a carborundum crystal is not linear—that is to say, the crystal, as a conductor, does not comply with Ohm's law, for the resistance of the crystal decreases as the current is increased. Hence the conductivity of the crystal is a function of the voltage acting on it (Fig. 17). Accordingly, if we pass a current from a local cell through a crystal under a voltage, say, of 2 volts, a telephone being inserted in series with the cell, and if we apply an oscillatory voltage also to the crystal, which varies, say, between +0·5 and −0·5 volt, then the crystal is alternately subjected to a voltage of 2·5 and 1·5 volts, but the corresponding currents would be, say, 8·4 and 1·8 microamperes, as shown by an experiment with one particular crystal employed by Prof. Pierce. The mean current would then be 5·1 microamperes, whereas the steady voltage of 2 volts would only pass a current of 4 microamperes. Hence, apart from the unilateral conductivity, and merely in virtue of the fact that the characteristic curve is not a straight line, we find that such a crystal, or even a confused mass of crystals, can act as a radio-telegraphic detector.

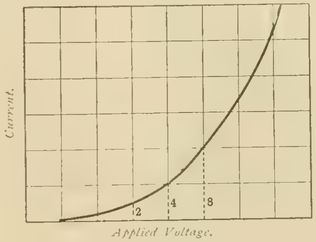

FIG. 17.

There are, therefore, two ways in which a crystalline mass of carborundum can be used as a radio-telegraphic detector. It consists of a conglomeration of crystals arranged in a disorderly manner, or not so symmetrically as to neutralise one another's unilateral conductivity. Hence the mass of crystals, like the single crystal, possesses unilateral conductivity, and also a conductivity which is a function of the voltage applied to it. We may then use it without a local cell, and avail ourselves of its valve property to rectify the trains of oscillations in the antenna and convert them into short unidirectional trains which can affect a galvanometer or telephone; or, secondly, we may place the crystal between the ends of a circuit containing a telephone and a shunted voltaic cell, and then on passing oscillations through the crystal we hear sounds in the telephone, due to the fact that the conductivity is a function of the voltage, and is therefore increased more by the addition than it is diminished by the subtraction of the electromotive force of the oscillations to or from the steady voltage of the local cell. The telephone, therefore, detects this change in the average value of the current by a sound emitted by it. Prof. Pierce has discovered that several other crystals possess similar properties to carborundum—for example, hessite, which is a native crystalline telluride of silver or gold; an anatase, which is an oxide of titanium; and molybdenite, which is a sulphide of molybdenum. As regards the origin of this curious unilateral conductivity, it seems clear that it is not thermoelectric, but at present no entirely satisfactory theory of the action has been suggested.

A number of forms of oscillation detector have recently been invented which depend on the curious fact that a slight contact between certain classes of conductors possesses a unilateral conductivity, and can therefore rectify oscillations. One such detector, now much used in Germany, consists of a plumbago or graphite point pressed lightly against a surface of galena. It has been found by Otto von Bronk that a galena-tellurium contact is even more effective. To the same class belongs the silicon-steel detector of Pickard. If such a contact is inserted across the terminals of a condenser placed in the receiving circuit, and if it is also in series with a telephone, the trains of oscillations are rectified or converted into more or less prolonged gushes of electricity in one direction through the telephone. These, coming at a frequency of several hundred per second, corresponding to the spark frequency, create a sound in the telephone, which can be cut up by the sending key into Morse signals. According to the researches of Prof. Pierce and Mr. Austin, it seems clear in many cases that this rectifying action is not thermoelectric, since the rectified current is in the opposite direction to the current obtained by heating the junction.

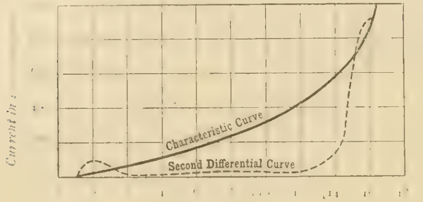

FIG. 18.—Characteristic Curve of Rarefied Gas Ionised by Hot Negative Electrode.

I may, then, bring to your notice some recent work on another form of radio-telegraphic detector, which I first described to the Royal Society about five years ago under the name of oscillation valve. It consists of an electric glow-lamp, in the bulb of which is placed a cylinder of metal, which surrounds the filament but does not touch it. This cylinder is connected to a wire sealed through the glass. Instead of a cylinder, one or more metal plates are sometimes used. The filament may be carbon or a metallic filament, and I found some year or more ago that tungsten in various forms has special advantages. The bulb is exhausted to a high vacuum, but, of course, this means it includes highly rarefied gas of some kind. When the filament is rendered incandescent it emits electrons, and these electrons or negative ions give to the residual gas a unilateral conductivity, as shown by me in a Friday evening lecture given here nineteen years ago. Moreover, the ionised gas not only possesses unilateral conductivity, but its conductivity, like that of the crystals just mentioned, is a function of the voltage applied to it. Hence, if we apply an electromotive force between the hot filament and the cool metal plate, we find that negative electricity can pass from the filament to the plate through the ionised gas, and that the relation between the current and voltage is not linear, but is represented by a characteristic curve bending upwards, which has changes of curvature in it (Fig. 18). The sharp bend upwards at one place implies a large increase in the current corresponding to a certain voltage, which means that, corresponding to a certain potential gradient, and therefore velocity of the electrons, considerable ionisation of the residual gas is beginning to take place. The current, however, would not increase indefinitely with the voltage, but would before long become constant or saturated.

It will be seen, therefore, that at points on the curve where there is a bend or change of curvature, the second differential coefficient of the curve may have a large value. Hence, if we consider the current and voltage corresponding to this point, it will be seen that any small increase in the voltage increases the current more than an equal small decrease in voltage diminishes it. If, then, we superimpose on a steady voltage corresponding to a point of inflexion of the curve an alternating voltage, the average value of the current will be increased. This, then, points out two ways in which this oscillation valve or glow-lamp can be used as a radio-telegraphic detector. First, we may make use of the unilateral conductivity of the ionised gas in the bulb and employ the glow-lamp with cylinder around the incandescent filament, as a rectifier of trains of oscillations to make them effect a galvanometer or telephone. This method was described by me in papers and specifications in 1904 and 1905. In that case the valve is arranged in connection with a receiving antenna, as shown in Fig. 19, and used with a galvanometer or telephone. Mr. Marconi subsequently added an induction coil and condenser, and employed in 1907 the arrangements shown in Fig. 20. In this case the trains of oscillations set up in the antenna could not by themselves affect a galvanometer or a telephone, but, when rectified by the valve, they become equivalent to an intermittent unidirectional current, and can then affect the telephone or a galvanometer, or any instrument for detecting a direct current.

On the other hand, we may take advantage, as I have more recently shown, of the non-linear form of the characteristic curve. In other words, of the fact that the conductivity of the ionised gas is a function of the voltage applied to it, and in the second method the valve and receiving circuits are arranged as shown in Fig. 21. In this case we have to apply to the ionised gas a unidirectional electromotive force which corresponds to a point of inflexion on the characteristic curve, and then to add to this voltage the alternating voltage of the oscillations set up by the incident electric waves in the receiving circuit. The result is to cause a change in the average value of the current through the telephone, and therefore to produce a sound in it, long or short, according to the number of trains of waves falling on the antenna. This last method, then, requires the application in the telephone circuit of an accurately adjusted steady electromotive force, not any electromotive force, but just that value which corresponds to a point on the characteristic curve at which there is a sudden change of curvature.

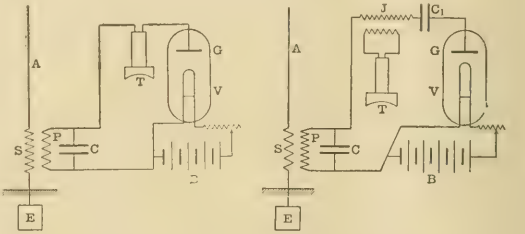

FIG. 19. FIG. 20.

Connections for Oscillation Valve used as Radiotelegraphic Detector.

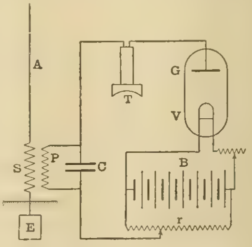

FIG. 21.—Connections for Oscillation Valve used as a Radiotelegraphic Detector.

At this point we may notice a broad generalisation which has already been made by H. Brandes, viz. that any materials such as the crystals mentioned, or ionised gases, which do not obey Ohm's law as regards the independence of conductivity on impressed voltage can be used as radio-telegraphic receivers. It is necessary to be able to test the relative sensibility of detectors to know whether any new form is an improvement. It is not always possible for an inventor to get these tests made at real wireless telegraph stations. Moreover, it is no use to test over short distances, because then all detectors appear to be equally good. I have found, however, that we can make these comparative tests very easily within quite moderate distances by employing closed sending and receiving circuits which are poor radiators. All the devices called wave detectors are really only oscillation detectors, and we can therefore test their value simply by ascertaining how feeble an alternating current or alternating voltage they will detect. If we, then, set up in one place a square circuit of wire a few feet inside, and complete the circuit by a condenser and a spark-gap, we can set up oscillations in it by means of an induction coil. I find that it is necessary to enclose the spark-gap in a cast-iron box, and to blow upon the spark with a jet of air to secure silence, absence of emission of electromagnetic waves direct from the spark balls, and constancy in the oscillatory circuit. I then set up, a few score or few hundred feet away, a similar tuned closed oscillatory circuit, and I connect the oscillation detector to be tested either in this circuit or as a shunt across the condenser. The closed receiving circuit is so constructed that it may be rotated round either of three axes. It is then generally possible to find some position of the receiving circuit such that no sounds are heard in a telephone connected to a highly sensitive detector associated with the circuit. This position is called the zero position. If the receiving circuit is rotated round some axis, it begins at a certain displacement to receive signals, and the angle through which it has to be turned is a measure of the insensibility of the particular oscillation detector being used. I find, for instance, that it is quite easy to take one of my oscillation valves, a magnetic detector, an electrolytic detector, a crystal detector, or any other type, and arrange these in order of their sensibility by means of the device described.

Sensibility is not, however, the only virtue which a wave detector should possess. It is important that it should be simple, easily adjusted, and not injured by the chance passage through it of any unusually large oscillatory currents. Another quality which is desirable is that it should be quantitative in its action, and that any change in the amplitude of the wave received should be accompanied by an equal change in the current which the detector allows to pass through the telephone. A quantitative oscillation detector, then, enables not merely signals, but audible speech to be transmitted. In other words, it can effect wireless telephony. The difficulties, however, in connection with the achievement of wireless telephony are not so much in the receiver as in the transmitter. We have to obtain, first, the uniform production of persistent electromagnetic waves radiated from an antenna, and next we have to vary the amplitude of these electric waves proportionately to, and by means of, the aërial vibrations created by the voice speaking to some form of microphone. We cannot employ an intermittent spark generator, because each spark would give rise to a sound in the telephone, and these sounds, if occurring at regular intervals, would produce a musical note in the telephone. If, however, we make the sparks run together into what is practically a high-voltage arc taking a small current, then, in an oscillatory circuit shunted across this arc, we have set up persistent high-frequency oscillations, as first achieved by Mr. Duddell.

We can greatly increase the energy of the oscillations by immersing the arc in a strong transverse magnetic field and also in a hydrocarbon gas, as shown by Poulsen, or we may employ a number of arcs in series. E. Ruhmer has lately also employed a high-tension arc between aluminium electrodes (Fig. 22), shunted by a condenser and inductance as a means of generating persistent oscillations. As an alternative, it is possible to create them by a mechanical method, viz. by a high-frequency alternator, subject, however, to certain limitations as to frequency. Both these types of generator have their advantages and practical objections. There is good evidence that radio-telephony has been accomplished over distances of 100 miles or more by each of these methods in the hands of experts, but what is now required is the reduction of the apparatus to such simple manageable and practical form that it can be applied in regular work. The wave-generating apparatus must be capable of producing uniform persistent oscillations of high voltage and frequency, not less than 30,000 or 40,000 per second, or at least above the limits of audition, and the amplitude of these oscillations must be capable of being varied by some form of speaking microphone placed in the oscillation circuit or in the radiating antenna, or in a secondary circuit coupled to it. No ordinary simple carbon microphone will safely pass sufficient current for this purpose. A type of multiple microphone has been used successfully, and also a duplex microphone, the invention of Ernst Ruhmer.

It is not, however, possible to speak of radio-telephony at the present time as having reached the same level of practical perfection as radio-telegraphy; but the possibilities of it are of such a nature that it will continue to attract the serious attention of inventors. This is not the place to enter into a full discussion of the causes which limit submarine telephony through cables, but there are well-known reasons in the nature of submarine cables as at present made which impose very definite limits upon it, owing to what is called distortion of the wave form. Electric wave telephony is free at least from this disadvantage, and if (as has been asserted) arc generators can be made self-regulating and capable of being worked for hours automatically, or even for ten minutes without being touched, then the remaining difficulties with the microphone are not insuperable.

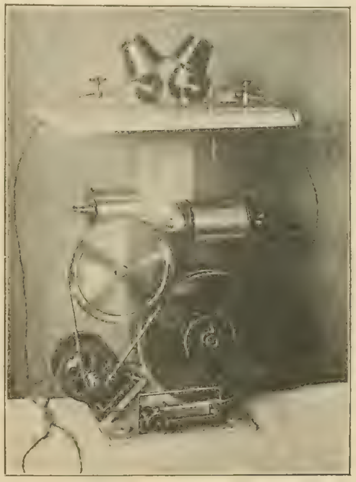

FIG. 22.—Ernst Ruhmer's High-tension Aluminium Arc for producing persistent Oscillations for Radiotelephony.

Time does not permit of the discussion of the many other points in connection with radio-telegraphy and telephony which have been the subject of recent work. Much attention has been paid lately to methods of cutting out atmospheric signals due to natural electrical discharges in the atmosphere, which are troublesome disturbers of the ætherial calm necessary for radio-telegraphy. Considerable thought and expenditure have been necessary to discover means for overcoming the difficulties of long-distance transmission by daylight, and also those arising from the cross-talk of other stations. Much also has been done in training skilled wireless operators both in the Navy and for the mercantile marine work. Radio-telegraphy, like aviation, is an art as well as a science, hence personal skill is a factor of importance in turning the flank of the difficulties of the moment. Nevertheless, the art and the science of radio-telegraphy are both progressing, and the splendid services already rendered by it in saving life at sea are at once a proof of present perfection and an evidence that the arduous labours of investigators and inventors have borne fruit in yet larger powers to command the great forces of nature for the use and benefit of mankind.

ILLUMINATING ENGINEERING.[1]

THIS society has been founded to bring together all those who are interested in the problems, practical and theoretical, of the *art of directing and adapting light, that prime necessity of* civilised, as well as of uncivilised, *existence, to the use and convenience of man.* To advance the subject of illuminating engineering, to investigate through all its lengthened breadth the facts within its domain, to increase and diffuse knowledge respecting them, and to unite those who are devoting their energies to these things, is the object of the society. The ascertained facts are few—all too few; their significance is immense; their economic and social value is great; but the ignorance respecting them generally is colossal.

For practically a century only have there been any systematic means of illumination in use in any civilised country. Before the year 1800 there were as means of illumination daylight, oil lamps, rush lights, tallow dips, and wax candles. Monarch and peasant, merchant-prince and workman, had alike to depend on individual sources of light at night. Only in the larger towns and cities was there any organised attempt to light the streets by oil lamps. In 1819 the authorities of the day stoutly resisted the proposal to light the then House of Commons by gas—nothing but wax candles could be admitted; but gas lighting was coming in, and Argand and colza oil lamps were the sole competitors until after 1850. Everything else dates since then—practically during the last half-century. For paraffin lamps were not widely spread until the 'sixties. Arc lighting, though tried for spectacular and lighthouse purposes from the 'fifties, did not come into public question until about 1879. Glow-lamps followed three or four years later. Still later came incandescent gas mantles and acetylene gas lights, while the newest things in both gas lighting and electric lighting are affairs of only a year or two ago. Many persons now realise the immense stride made in the introduction of the Auer (Welsbach) mantle for incandescent gas; very many fewer people realise the significance of the corresponding step forward that has been begun by the introduction of the metallic filament glow-lamp. We are on both sides in the very middle of an immense evolution in the art of illumination.

But whilst the means of illumination have thus been developing with amazing strides during a single generation, and the organised systems of distribution by municipal and urban and rural authorities, and by private corporations, have ramified throughout the community and brought supplies of gas and of electricity—shall I also say of oil?—to our doors, there has been another and very different development going on. I refer to the growth of that branch of the science of optics which deals with the measurement of luminous values. Photometry has been growing into an exact science by the explanation of its laws and the improvement of the instruments of measurement. It was not until 1760 that the first real discussion of photometric principles was made known. In that year Lambert, in his "Photometria," laid down the fundamental laws, and likewise in the same year Bonguer gave to the world his "Traité d'Optique," wherein a primitive photometer was described. Rumford's shadow photometer was invented in 1794, and Ritchie's in 1824. Then comes a long gap. Save for Bunsen's over-rated grease-spot instrument, there was no important advance in photometry until the 'eighties, when there were produced many novel forms, some of them, including the now well-known forms of L. Weber, Lummer-Brodhun, and Rood, capable of yielding results of much higher precision in the comparison of different sources of light; also in the 'eighties we meet for the first time with special forms of photometer of the kind destined to play a very important part in the work of our society, many photometers measuring the values, not of the brilliancy of a source of light, but the illumination of a surface.

Our primary concern is the adequate and proper illumination of things; and as we have to reduce the present chaos to an exact science, our first business is to secure some common agreement as to the measurement of illumination and the establishment of reasonable rules as to the amounts of illumination required in different cases.

Foremost, then, in the programme of work for our society we put the question of the units of measurements and the promulgation of the proper definitions of them. We must secure agreement—national and, if possible, international—as to what shall be taken as the unit of light and what as the unit of illumination at a surface.

Happily, the long-standing controversy as to the former appears to be settling itself by at least a preliminary agreement between the standardising laboratories of the great nations. One "candle" is no longer to be a vague and indefinite thing. The new definition provisionally agreed upon is an ideal unit, in terms of which one can describe the several standards in use in different countries. If this provisional *entente* can but be ratified by a little international common sense, we shall have henceforward an international "candle" such that it is the same in England as in America, equal to the *bougie décimale* accepted in France, and related to the Hefner-candle of Germany in the precise proportion of ten to nine.

But we have still to find agreement on the standard of illumination. Here in England, and in the United States, we have already grown accustomed to describe amounts of illumination of surfaces in terms of a British unit—the "candle-foot"—not perhaps a very happy term—one that we would readily exchange for a better—meaning, thereby, the intensity of the illumination at a surface situated at the distance of one foot from a light of one "candle." The source being assumed here to be concentrated at a point, the law of inverse squares holds good.

Adopting the candle-foot as the unit of illumination, one may readily state certain facts with definiteness. All competent authorities are agreed that at night, for the purpose of reading, an illumination is required not less than one candle-foot, some authorities saying $1\frac{1}{2}$ candle-foot. The facts appear to be that reading is impossible with an illumination of one-tenth candle-foot, difficult and fatiguing with one of one-fifth candle-foot, comfortable with from $1\frac{1}{2}$ to 3 or 4 candle-foot, but that if the illumination exceeds 6 or 8 candle-foot, the glare of the page is again fatiguing and dazzling. The page should neither be under-illuminated nor over-illuminated. Something depends, it is true, on the size of the print. Under a feeble illumination of, say, $\frac{1}{2}$ candle-foot, a type of pica size printed in a fount of bold face properly inked is legible when one of long-primer size, printed in a weak way, would be practically illegible. Something also depends on the state of the eye as affected by the general illumination of the surroundings. Very seldom does one find in any ordinary room an artificial illumination exceeding 3 candle-foot. By day, on a writing-table placed near a north window—or near any window not receiving direct sunlight—the illumination may exceed 3, and may even attain 4 or 5 candle-foot.

Until a unit of illumination was thus agreed upon, it was impossible to render any reasonable certainty to estimates of the amount of illumination in any case of dispute. What is the meaning of the term well-lit as applied to any room, building, factory, workshop, or school? Formerly the term was entirely vague. To-day the answer can be given in numerical terms. Formerly judgment had to be made by the unaided eye, and the eye is notoriously a bad judge. As between two different illuminations, the powers of discrimination of the eye are very limited. The eye can equate, but it cannot appraise. It can tell with fair accuracy whether two adjacent patches are equally bright; if they are not equally bright it cannot say with any kind of proportionality what their relative brightnesses are. All photometry depends on the perception of an equality.

---

[1] Abridged from the inaugural address delivered at the inaugural meeting of the Illuminating Engineering Society held on November 18, by Prof. Silvanus P. Thompson, F.R.S., president of the society.

Photometers for the measurement of illumination have been mentioned earlier as coming first into notice in the 'eighties. One of the earliest in this country was that constructed by Sir William Preece, with the assistance of Mr. A. P. Trotter, for measurement of the illumination of side-walks and pavements of streets. It has been subsequently developed by Mr. Trotter, and as constructed by Mr. Edgcombe is a most useful and handy instrument, telling the amount of illumination directly in terms of the candle-foot. Another, by Mr. Haydn Harrison, measures the illumination, not on the horizontal, but at 45°. Almost equally early with the Preece-Trotter illumination photometer was the school photometer of Petruschewsky, apparently little known in this country. Most recent of this sort is the form due to Martens.

The principles and construction of photometers are matters that have interested me for nearly thirty years. About 1880 I brought out a form of wedge-photometer (modified from Ritchie's form), in conjunction with Mr. C. C. Starling, for electric light measurements. Later I gave to the Physical Society an investigation of the errors arising in photometry from the almost universal assumption that the law of inverse squares is fulfilled. In 1882, when lecturing at the Crystal Palace Exhibition, I gave diagrams to show the effect of the superposition of illumination from two or more lamps, and discussed the variations of illumination in a street between the places of maximum and the places of minimum illumination. Twelve years ago I described a tangent photometer, which has remained a mere optical curiosity.

No one can have worked at the photometry of modern lamps, or of the illumination of surfaces lit by lamps, without becoming conscious how much misunderstanding there is of the elementary laws of illumination. There is Lambert's cosine law, admirable and simple if only it were not in so many cases vitiated by the presence of organised—that is, specular—reflection. There is the law of inverse squares, itself a universal geometrical law of action radiating from a point, so fatally and absolutely misleading if applied to any other case than that of action from a point.

One subject on which more information is badly needed is the specific brightness of surfaces of different kinds when subjected to a standard illumination. For instance, how much light is reflected, per square inch, when illuminated with an intensity of 1 candle-foot, from such materials as oak panelling, whitewash, brown paper, or the surface of a red brick wall? Here in this theatre the walls are tinted of a dark Pompeian red or maroon, which reflects but little light. The extra annual expense on lighting that might be saved had a lighter tint been used is surely worth considering.

The subject of diffuse reflection which here comes into play has indeed been investigated partially by several persons. There are Dr. Sumpner's researches of 1894 and those of Mr. Trotter on white cardboard and other white matt surfaces, but how few others! Again, there is the subject of diffuse refraction, which occurs in ground-glass shades, ribbed and corrugated glass panes, and other devices for diffusing the concentrated light of lamps. Yet how little does any optical book tell us on the subject of diffuse refraction. Reflection and refraction as they occur at dull or irregular surfaces appear to be of no importance to the academic writer of text-books of optics, but they are of vital interest to the illuminating engineer. Again, there are a number of semi-physiological problems that demand investigation and settlement. We all know that our eyes have an automatic diaphragm which stops down the entering light to protect our eyes from glare, rendering us relatively insensitive to bright lights. Does anyone know whether the contraction of the pupil depends on the total amount of light entering the eye or on the intensity of the image on local patches of the retina?

Again, we all know how an unshaded arc-lamp, or even glow-lamp, "cuts" the eyes by the very concentration of its beams, even when it may be many feet away, while the same actual amount of light, if diffused over a greater apparent surface, as by a surrounding globe of ground glass, is quite readily endured, and does not produce the same painful sensation. Does anyone know how great is the specific brightness of surface that the eye will tolerate without experiencing this discomfort? We can look at a white cloud or at the blue sky without pain. Can we endure a specific brightness of so much as one-tenth of a candle per square inch?

Our eyes are provided by nature with a most exquisite and automatic iris diaphragm which opens in the dark and closes in the light, thereby shielding us partially against the evil effects of glare. Putting it in the language which the photographer uses to describe the stopping-down of a camera-lens, the automatic iris of our eye can close the pupil so that while in a comparative darkness the aperture opens to *f*/2 or *f*/2·5, it closes, amid a brilliant surrounding illumination, to about *f*/20. Suppose we are looking out in relative darkness, and are confronted with a brilliant patch shining with a specific brightness of one-tenth of a candle per square inch, we shall feel a certain amount of discomfort from its glare, and if we regard it steadily for a second or two will, on closing our eyes or turning away, see those persistent coloured images that trouble us after looking at any very bright light; but now let the same brilliant patch be placed against a bright background. Far more light will enter the eye; the automatic iris of the eye will in a few moments have contracted, stopping down the lens of the eye so that it will be far less sensitive. In these circumstances, will the patch that has a specific brightness of one-tenth candle per square inch pain or dazzle the eye? I ask the question, but I do not know the answer. Does anyone know what the answer ought to be? It is a simple question, and a few experiments would soon settle it. Of course, one must admit that the automatic action of the iris diaphragm, important as it is, does not by any means account for the whole of the facts about the want of proportion between the intensity of a stimulation and the intensity of the resulting sensation. Fechner's logarithmic law of psychophysics gives a clue, but even this does not seem capable of expressing, much less of explaining, the facts about the observed want of proportionality. Why should a light of ten-fold brilliancy not produce a sensation ten times as intense? And why should a greater brightness of the general surroundings relieve us of the annoyance of those coloured after-images? After-images can be seen even under extremely feeble illumination, as I have again and again found. Has anyone discovered any exact law governing their occurrence?

All these queries show that there is plenty of work awaiting us, even in the mere collection and completion of such scattered information as is already available; but there are even more important questions before us, more important, not in science, but in their relation to the public welfare and the economics of the community.

Now that we have a standard of illumination and simple portable instruments that will measure it, there can be no excuse for inaction or ignorance in applying that knowledge to securing proper illumination for public and private buildings.

Let me begin with school buildings. They are the most important; for whatever bad results flow from bad lighting of churches, factories, or railway stations, those which result from the bad illumination of schools are far more to be deplored—they imperil the eyesight of the next generation.

All ophthalmic surgeons agree that the cause which forces the children into increasing shortsightedness is protracted poring over books under an insufficient illumination. Even in what an inspector might call a well-lit school the illumination at the surface of the desk may be quite insufficient if the desks are badly placed, or the windows insufficiently high, or the lamps badly distributed.

All educational authorities ought henceforth to insist on rational requirements as to lighting. Hitherto they have had nothing definite to specify; now that illumination photometers are available, they ought to require a minimum of $1\frac{1}{2}$ candle-foot at the worst-lighted seat in the schoolroom, and not depend on purely architectural rules about heights of windows or areas of window-space. In England the Board of Education, in its Building Regulation (1907), Rule 6, clause *c*, has laid down a foolish rule:—"Skylights are objectionable. They cannot be approved in school-rooms or class-rooms." That perfectly monstrous provision ought to be at once repealed. The universal experience of the textile industries, where adequate lighting of spinning and weaving machinery is a prime necessity, is that no method of lighting is so satisfactory as skylights in roofs specially constructed to receive light from the northern sky.

Hitherto little attention has been paid by either local or central authorities to conditions affecting the lighting of factories and workshops. It is true that the factory inspectors require periodic whitewashing of factories, but that is for sanitary reasons, not primarily to secure better illumination. The Home Office has its regulations as to temperature and degree of moisture required or permissible in the different classes of factories and workshops. Then why not also similar regulations as to the proper amount of illumination? Surely the eyesight of the workers is as well worth protecting from injury as their lungs and their limbs. So far as I am aware, Holland is the only country in which legislation has fixed a statutory amount of illumination in factories, the figure there being from 10 to 15 candle-metre, equivalent, therefore, broadly to the value of 0·9 to 1·35 candle-foot.

Architects are often blamed for deficiencies in the lighting of the buildings they design, perhaps more often for the deficiencies found at night by artificial lighting than for those of the lighting by day. For this the fault rests no doubt largely with the persons who have installed the lighting arrangements, and one must not blame the architect too severely for having been as ignorant as all the rest of the world about the principles of illumination; but henceforward, when once it is known how much illumination is required in the rooms of different kinds, the architect ought in his specification to set down, with appropriate numerical values, what degree of illumination is required in the various parts of his building.

I venture to suggest that it would be a good thing if, in the public interest, our society, or some committee appointed by it, could draw up a model specification, or model clauses for architects to insert in their specifications, in which the proper way of prescribing the requisite amounts of illumination in different classes of cases should be set forth.

Outside all these matters of more public interest, there are topics enough to occupy our society for many months to come. We shall have discussions on several interesting subjects during next spring, and there are many problems awaiting solution. When all else fails us, we can turn to the eternal question of the measurement of colour. We have also the long outstanding problem of the production of light without heat, accomplished in nature by the fire-fly, but unrealised by any artificial lamp. We might turn to discuss special cases, such as the flashing lights of lighthouses, or the special lights needed in the hospital for the detection of rashes or the treatment of disease. Amid such endless ramifications of our subject there is no fear of coming to a premature end of our programme. There is, indeed, abundance of work before us.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Dr. Baker has been appointed chairman of the examiners for part ii. of the mathematical tripos; Mr. A. Hutchinson, chairman of the examiners for the natural sciences tripos; and Mr. H. W. V. Temperley, chairman of the examiners for the economics tripos, 1910.

Mr. A. E. Shipley has been appointed a manager of the Balfour fund.

Mr. J. E. Purvis has been appointed university lecturer in chemistry and physics in their application to hygiene and preventive medicine for five years.

The Walsingham medal for 1909 has been awarded to Mr. L. J. Wills, for his essay entitled "The Fossiliferous Lower Keuper Rocks of Worcestershire," and a second medal to Mr. H. H. Thomas, for his essay entitled "The Leaves of Calamites (Calamocladus section), with Special Reference to the Conditions under which they Grew."

It is proposed that a grant of 100*l.* be made from the Worts fund to Mr. J. Romanes towards defraying the expense of a journey to Costa Rica with the object of studying the geology and geography of that country.

THE Earl of Crewe, chairman of the governors of the Imperial College of Science and Technology, will distribute the diplomas, medals, and prizes to the successful students at the Royal College of Science on Thursday next, December 16. Prof. Adam Sedgwick, F.R.S., will deliver an address.

DR. H. A. MIERS, F.R.S., principal of London University, will distribute the prizes and certificates at the Sir John Cass Technical Institute, Aldgate, on Thursday, December 16. There will be an exhibition of students' work and apparatus in the laboratories, workshops, and other rooms of the institute.

A CONFERENCE to discuss the needs of technical education in Burma was held at Rangoon early in November. We learn from the *Pioneer Mail* that Mr. J. G. Covernton, Director of Public Instruction, in opening the discussion, presented a brief sketch of what had been done in the past in the way of technical education. He divided the work of technical instruction into two main groups:—(1) those connected with scientific professions, especially engineering; (2) those connected with ordinary country and home life. He proposed that a central technical school for industrial education in the vernacular should eventually be opened at Insein in connection with the engineering school, and related to all the selected vernacular schools for technical education which may hereafter be established, and that pupils who showed special aptitude for technical training should be drafted to this central school. The instruction should be in the vernacular, and its aim be to provide for a general technical training for hand and eye. For trained pupils who might hope to be skilled artisans in various crafts and industries there should, the director said, be local industrial schools in local industries.

THE report for 1908–9 on the work of the Department of Technology of the City and Guilds of London Institute has just been published. It abounds in interesting information concerning the useful work being accomplished by the department in the way of improving the technical education of the country. At the last examinations held by the department, 23,399 candidates were presented in technology from 404 centres in the United Kingdom, and of these 13,665 passed. By the aid of advisory committees the institute is enabled, the report points out, to promote useful relations between trade organisations and the schools in which artisans and others receive their technical instruction. The institute, too, has a system of inspection of trade classes by professional experts, and during the session under review 107 centres were visited by members of the institute's staff for the examination, inspection, or organisation of classes. The report also states that the independent criticisms from examiners in wholly distinct subjects show that many teachers, while undoubtedly using their best efforts to acquaint the students with the technical details of their trade, fail to obtain good results owing to their giving instruction on wrong lines, paying too much attention to description and too little to the theory of the subject and to the principles underlying the work in which they are engaged. This may be partially due to lack of experience in teaching and failure to realise the difficulties of their students, and in such cases a visit from an inspector, himself an experienced teacher in the same subject, would often do much to remedy the defects, more especially if the visit can be repeated so as to enable the instructor to avail himself of the inspector's experience from time to time in the difficulties that arise. The institute also concurs in a suggestion, made by its inspectors, that if the education authority could send a comparatively inexperienced teacher to visit some of the schools at which successful classes are conducted and see their methods of work, such a visit would amply repay its cost.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 25.—Sir Archibald Geikie, K.C.B., president, in the chair.—Sir W. de W. **Abney**: The change in hue of spectrum colours by dilution with white light. The author shows that by diluting the spectrum colours from the red to the green-blue with moderate percentages of white light, their hue travels towards the yellow, the change being dependent on the amount of red and green existing in the white added. At a point near λ 5780 the hue remains unaltered by the addition of white, and it is towards this point in the spectrum that the colours on each side of it travel. It is pointed out that this change in hue enables the relative amounts in green and red from λ 5000 to λ 6000 to be accurately determined.—Prof. G. E. **Hale** and F. **Ellerman**: The nature of the hydrogen flocculi and their structure at different levels in the solar atmosphere.—Prof. H. L. **Callendar** and H. **Moss**: The boiling point of sulphur corrected by reference to new observations on the absolute expansion of mercury.—C. **Cuthbertson** and Maude **Cuthbertson**: The refraction and dispersion of neon. The refractivities of neon (Ne_2) for different wave-lengths are found experimentally to be

$\lambda \times 10^8$	$(\mu - 1)10^6$
6438	134·02
5461	134·30
4800	134·63

These can be expressed by the formula

$$\mu - 1 = \frac{5·133 \times 10^{27}}{38517 \times 10^{27} - n^2}$$

where n is the frequency V/λ. Owing to the feebleness of the dispersive power of neon, the accuracy of the value obtained for the dispersion is not to be relied on to less than 5 per cent. Revised formulæ for the refractive indices of helium, argon, krypton, and xenon are given, in the same form, which supersedes the use of Cauchy's formula.—C. **Cuthbertson** and Maude **Cuthbertson**: The refraction and dispersion of air, oxygen, nitrogen, and hydrogen, and their relations. The refractivities of these gases for different wave-lengths are found experimentally to be

$\lambda \times 10^8$	$(\mu - 1)10^6$			
	Air	Oxygen	Nitrogen	Hydrogen
6563	291·92	269·75	298·16	138·66
5790	292·98	270·99	—	139·33
5461	293·60	271·70	299·77	139·71
4861	295·11	273·45	301·21	140·64

Cauchy's formula of two terms is shown to be inadequate to express the dispersion of a gas, and a formula of Sellmeier's type is adopted,

$$\mu - 1 = \frac{C}{n_0^2 - n^2}.$$

In this form the refractivities of these gases are given by the constants shown in the table below. Revised values of the indices of sulphur, phosphorus, and mercury, expressed in the same form, are also given, and it is shown that, on the electronic theory of dispersion, the relative numbers of "dispersion electrons" in hydrogen, oxygen, and nitrogen are as 1, 2, and 3 almost exactly; in sulphur and phosphorus, to a less degree of accuracy, as 3 and 4½. In mercury the number is in the neighbourhood of 4½ to 5.

	$C \times 10^{-27}$	$n_0^2 \times 10^{-27}$	V	C/V
Air	4·6463	16125	—	—
Hydrogen	1·692	12409	1	1·692
Oxygen	3·397	12804	2	1·699
Nitrogen	5·0345	17095	3	1·678
Sulphur	4·808	4600	3	1·603
Phosphorus	7·61	6534	4½	1·691
Mercury ... to	7·82 8·371	4360 4740	4½ 5	1·74 1·68

—C. **Cuthbertson** and Maude **Cuthbertson**: The refraction and dispersion of sulphur dioxide and hydrogen sulphide, and their relation to those of their constituents. The refractivities of sulphur dioxide for different wave-lengths are found experimentally to be

$\lambda \times 10^8$	$(\mu - 1)10^6$
6700	656·40
6500	657·10
5800	661·26
5461	663·97
5000	668·63

These can be expressed in a formula of Sellmeier's type,

$$\mu - 1 = \frac{5·728 \times 10^{27}}{8929 \times 10^{27} - n^2}.$$

The refractivities of hydrogen sulphide for different wave-lengths are found experimentally to be

$\lambda \times 10^8$	$(\mu - 1)10^6$
6563	636·22
5790	641·17
5461	644·03
4861	650·98

These can be expressed in the same form by

$$\mu - 1 = \frac{4·834 \times 10^{27}}{7808 \times 10^{27} - n^2}.$$

The number of "dispersion electrons" in SO_2 is shown to be approximately equal to the sum of the numbers of "dispersion electrons" in S_1 and in O_2. The number of "dispersion electrons" in H_2S is, approximately, one more than the sum of the "dispersion electrons" in H_2 and in S_1.—Prof. M. F. **Fitzgerald**: Flapping flight.—Dr. W. **Rosenhain** and J. C. W. **Humfrey**: The crystalline structure of iron at high temperatures. The paper contains a preliminary account of observations on the effects of strain on iron at high temperatures. Polished strips of nearly pure iron were heated *in vacuo* and strained while hot, the central portions of the specimen attaining a temperature of about 1100° C., while the ends remained below visible redness. Heating alone produced a surface pattern caused by a volume change in the metal when passing through the $\alpha = \beta$ transformation, and occasionally where the temperature was highest a slight tarnish which revealed the γ crystals. Heating and straining *in vacuo* showed that at all temperatures attained deformation took place by means of slip on the gliding planes of the crystals; three distinct regions could, however, be distinguished, and temperature estimations by the method of Joly's meldometer agree with the identification of these regions with the α, β, and γ ranges of Roberts-Austen. This identification is supported by differential heating and cooling curves given in the paper. In the α range the number and intensity of slip-bands increases rapidly with increasing temperature; at the transition point—which is seen as a well-defined line across the specimen—the bands suddenly cease and remain minute during the β range; in the γ range the bands are again numerous, but differ from those observed in the α range by their straightness and regularity and by the frequent occurrence of twin crystals. These observations are illustrated by three photomicrographs. The authors consider that their observations strongly support the allotropic theory of Roberts-Austen, particularly since they show that β iron, although at a higher temperature, is markedly harder and stronger than α iron. So much is this the case that when such a specimen was broken while hot, the fracture took place in the region of hottest α iron, just before the transition point. The present observations also demonstrate the similarity of γ iron, as found in nearly pure iron when heated, with the well-known "γ iron" found in alloy steels.—Dr. A. E. H. **Tutton**: The relation of thallium to the alkali metals: a study of thallium-zinc sulphate and selenate. This communication contains the results of an investigation of the thallium salts of the zinc group of the monoclinic series $R_2M\left(\begin{matrix}S\\S_e\end{matrix}O_4\right)_2.6H_2O$, analogous to the previous investigation of the simple rhombic salts of the series $R_2\begin{matrix}S\\S_e\end{matrix}O_4$. The conclusions formed as the result of the latter research are fully confirmed and independently substantiated, as regards the relations of thallium to the alkali metals and ammonium, and the nature of the isomorphism existing between the salts of these various bases. A large number of crystal measurements and determinations of physical constants are recorded in the paper. The main conclusion is that the morphological and physical properties of the crystals of these thallium double salts are such as quite entitle them to inclusion in the monoclinic isomorphous series of the general formula above given, but not to places in the more exclusive eutropic series within that isomorphous series. This eutropic inner series is confined to the salts the interchangeable metals of which belong to the same family group of the periodic classification, namely, to those of potassium, rubidium, and cæsium, the crystals of which exhibit the regular progression of angles and physical constants, according to the atomic weight of the metal, already pointed out by the author in previous communications. The crystals of the thallium salts resemble very closely those of the ammonium salts—which are also outside the eutropic series, but are included in the isomorphous series—except as regards one outstanding specific property, that of refraction; for the crystals of the thallium double salts, like those of the simple sulphate and selenate of thallium, exhibit transcendent refractive power, which proves to be a characteristic property of the crystals of all the thallium salts yet studied by the author.—P. F. **Everitt**: The nature of the diffraction figures due to the heliometer. This paper contains a discussion of the heliometer diffraction fringes. The matter is one of considerable importance, owing to its bearing on astronomical measurements taken with this instrument. A difficulty arose owing to the appearance of these fringes in heliometer work on an artificial double star. It was then found that, although the subject had been discussed by Bessel, Hansen, and Gauss, a good photograph of the actual fringes obtained by Scheiner and Hirayama, and a series given for the calculation of the fringes by Bruns, all attempts at their actual numerical determination had failed, owing to the extremely slow convergence of the series adopted, at a small distance from the centre of the system. By the adoption of a semi-graphic method, and the use of mechanical integrators, it has been found possible to carry out the calculations needful in order to obtain an accurate picture of the fringes. Photographs were taken of the fringes, and these, taken by the author, as well as the photograph taken by Scheiner and Hirayama, show a close agreement with the calculated contours, and enable one to obtain the proportions of the central (non-elliptic) oval, with which observers are chiefly concerned. The close agreement between the calculated and theoretical values of the different parts of the system is a further proof that the old undulatory theory suffices to determine in practice the true dimensions of such diffraction figures.—E. **Cunningham**: The motional effects of the Maxwell æther-stress. There is an outstanding gap in electromagnetic theory in respect to the attempt to reconcile the analysis of æthereal stress on the lines initiated by Maxwell with Newton's third law and with the law of the conservation of energy. In the present condition of theory there are assigned to the æther certain distributions of electromagnetic energy and momentum. The hypothetical distribution of energy is necessarily associated with the Poynting vector which measures its rate of transference. The distribution of momentum is so defined that the rate of increase of the total amount within any given volume supposed at rest in the æther is equivalent to the resultant of the Maxwell stresses on the bounding surface. There is, however, no connection established between the transference of energy across an area and the stress across that area. Such a connection would require that it should be possible to assign to the medium in which stress and energy reside a state of motion whereby the stresses might do the necessary amount of work; and this, again, would require the revision of the specification of stress, inasmuch as the ordinary expressions are computed for an element of surface which is at rest. In the first section of the present paper it is shown that, if g is the intensity of electromagnetic momentum ($[EH]/4\pi c$) and w the energy intensity ($[E^2+H^2]/8\pi$), and the velocity v is taken in the direction of g of magnitude, such that $(c^2+v^2)g=2v\mathrm{W}$, the same stress system which would account for the transfer of momentum will account for the transfer of energy, provided the æther is assumed to be moving with velocity v. The stress system is not the ordinary Maxwell one, but reduces to it in the electrostatic case. In this case it is known that the Maxwell stress may be analysed into a tension along the lines of force, together with a uniform pressure at right angles to those lines. This property of the stress system, commonly given, is not true of the total stress (electric and magnetic) in the general field. It is shown, however, that the stress system obtained in the paper can always be reduced to this form. The direction of one of the principal stresses is always along the velocity v. It is shown, further, that at the surface of a perfect reflector, stationary or moving, the velocity v is equal to that of the reflector combined with a velocity tangential to it, that is to say, a perfect reflector is analogous to an impenetrable boundary. In the second part of the paper a similar analysis is applied to radiation such as would exist in the interior of a cavity the walls of which are moving, so that, although the electric and magnetic forces vary extremely rapidly and in an irregular manner, there is necessarily a transfer of energy. Taking ϵ and γ as the mean values of the energy and momentum over intervals of time, which are short as compared with those which are appreciable by mechanical means, but long as compared with the period of the irregular fluctuations which constitute natural radiation, it is found that the mechanical properties of the radiation may be represented as those of a continuous quasi-fluid, in which there is a definite pressure p at every point (the same in all directions) and a definite velocity v, the relations connecting the several quantities being

$$3p=\epsilon-v\gamma \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$c^2\gamma=v(\epsilon+p) \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

If a small volume V is followed in its motion with the quasi-fluid, it is found that the quantity

$$p\mathrm{V}^{4/3}(c^2-v^2)^{-2/3} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

remains constant. If v^2 is neglected this becomes the known equation connecting the pressure and volume of steady radiation for adiabatic changes. Finally, it is shown that if a state of the radiation differing slightly from the actual is conceived, and dQ is the difference in the energy of the small volume V, after allowing for the change due to mechanical causes, such as increase of momentum and volume, the condition that the expression dQ/T should be a perfect differential is that

$$p(c^2-v^2)^2=k\mathrm{T}^4 \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

This with (3) involves the equation

$$p\mathrm{V}/\mathrm{T}=\text{constant}.$$

—Dr. H. C. **Pocklington**: The aberrations of a symmetrical optical instrument. The doubly modified characteristic function is written down, and the singly modified function derived from it correct to terms of the fourth order of small quantities. This is transformed so as to take account of the existence of an exit pupil, and formulæ are found giving the aberrations for any position of the object and pupil in terms of the six coefficients of aberration of the system. Some relations are found between these aberrations, and connection is established with the methods of numerical calculation given in Whittaker's tract on "The Theory of Optical Instruments."—H. E. **Watson**: The spectrum of radium emanation.—Prof. E. G. **Hill** and Dr. A. P. **Sirkar**: The electric conductivity and density of solutions of hydrogen fluoride.—Sir David **Bruce**, Captains A. E. **Hamerton** and H. R. **Bateman**, and Captain F. P. **Mackie**: Sleeping sickness in Uganda. Duration of the infectivity of the *Glossina palpalis* after the removal of the lake-shore population.

Institution of Mining and Metallurgy, November 18.—Mr. Edgar Taylor, president, in the chair.—L. D. **Ricketts**: Experiments in reverberatory practice at Cananea, Mexico. A detailed description of the installation of a reverberatory furnace and McDougal calciners at the Cananea Consolidated Copper Co.'s Works, and of the difficulties that were encountered in connection with the fuel available. The coal that was obtainable was of so unsuitable a quality that, after experiments with it whole and pulverised, none of which was attended with success, recourse was had to oil fuel. A feature of the smelting operation is the relatively large proportion of flue dust treated. Full details are given of the quantities of materials treated and of the costs of the various operations, and the author goes minutely into the circumstances attending the failure of the coal-firing and difficulties encountered during that and the subsequent oil-firing. The paper is principally composed of observed facts.

Physical Society, November 26.—Dr. C. Chree, F.R.S., president, in the chair.—Dr. J. W. **Nicholson**: The effective resistance and inductance of a helical coil. This paper deals with a determination of the effective resistance and inductance of a helical coil of great length, composed of thin wire, wound on a cylinder the radius of which is large in comparison with that of the wire. The pitch of the winding is not small, so that the problem cannot be treated by the method of Cohen. The method employed depends upon the use of a type of "helical coordinates" defining the position of any point, and of the general theorem relating to orthogonal systems of coordinates. A solution is obtained for the internal and external forces, corresponding to a given impressed electromotive force, in the form of a Fourier series of which only the initial terms require calculation. The value of the effective current across any section is obtained, and thence the inductance and resistance. For a high frequency it is found that the change of self-inductance due to twisting of the wire tends to vanish, and that the change of resistance tends towards a value independent of the frequency.—W. A. **Scoble**: Ductile materials under combined stress. The author further considers the results from some earlier tests made on mild steel bars, ¾-inch diameter and 30 inches effective length, under combined bending and torsion. It is pointed out that the yield-point is usually selected as the criterion of strength, because it is more easily determined than the elastic limit, it is less affected by special treatment of the material, and it is assumed that the failure of Hooke's law between the elastic limit and the yield-point is due to local yielding. The elastic limit is the correct point, and is used throughout, because the intermediate state mentioned above does not appear in bending. The results of tests on steel and copper tubes under combined bending and torsion are also given. All the results indicate that the maximum stress and maximum strain laws do not apply to ductile materials. The stress difference or shear stress law is approximately true, but there is, in each case, a deviation from the law which is opposed to the other theories mentioned. The shear stress law appears to state the average behaviour of ductile materials, but there are considerable deviations from the law, which are usually opposed to the other theories. Other tests by the author indicate that brittle materials obey the maximum stress law, and it is therefore suggested that the value of "m" depends chiefly on the degree of ductility of the material considered, and to a lesser extent on the system of loading.—Drs. W. **Makower** and S. **Russ**: The recoil of radium C from radium B. It has been shown in a previous paper that, during a radioactive transformation involving the expulsion of an α particle, the residue of the atom from which the α particle has been expelled recoils in an opposite direction to that in which the α particle is emitted, and can travel a considerable distance through a gas if the pressure is sufficiently low. A similar effect was also demonstrable in the case of the transformation of radium B into radium C, although this transformation is supposed to be accompanied by only β rays. The phenomena associated with this recoil are studied in this paper. In the first place, it was found that it was only in certain circumstances that pure radium C free from radium B was projected from a plate coated with radium B and radium C. Secondly, the active deposit on a plate appears to be concentrated into heaps, so that radium C, in breaking up, mechanically carries with it some radium B. If, however, sufficient time is allowed after removing a plate from the emanation for Radium A to decay completely, and if, further, sufficiently small quantities of deposit are used to avoid the formation of heaps, practically pure radium C is emitted. The law according to which the radiation fell off with distance was also studied, and it was found that radium C is not emitted from an active plate equally in all directions, a greater quantity being emitted normally to the plate than in directions making an angle with the normal. The absorption by air of radium C when it recoils from radium B was investigated. It was found that about half the radium C projected from a plate was stopped by 2·5 cm. of air at a pressure of 0·04 mm. mercury. Since radium B emits only β particles, the energy of recoil in this case should be less than one-millionth of the energy of recoil in a transformation in which an α particle is emitted. The fact that the penetration of radium C when it recoils is as much as one-fortieth of that previously found for radium A and radium B is therefore surprising.—Dr. C. V. **Burton**: The sun's motion with respect to the æther. Notwithstanding the well-known "principle of relativity," it is theoretically possible to determine the motion of the solar system with respect to the æther from observations of the eclipses of Jupiter's satellites, and the possibility was indicated by Maxwell some thirty years ago. For convenience, the motion of the æther with respect to the sun may be called a wind, and the method proposed is based on the consideration that the tidings of an eclipse will travel towards us more rapidly when the Jovian system is to windward of us than when it is to leeward. The residual discrepancies between the observed and calculated times of eclipses have to be analysed for systematic differences depending on the direction in space of the straight line drawn from the earth to Jupiter, and formulæ are given for finding by the method of least squares the most probable values of a, b_1, c_1, the components of the sun's velocity with respect to the æther. The material available is to be found in Prof. R. A. Sampson's discussion of the Harvard photometric eclipse observations, about 330 eclipses of Jupiter's satellite I. being included. In order to obtain a preliminary notion of the accuracy to be expected, a simplified system has been considered in which (for one thing) the eccentricity of the orbits was virtually neglected, and it appears that some advantage is to be gained by taking the plane of Jupiter's orbit, rather than the ecliptic, as one of the coordinate planes. The axis of x is drawn from the sun's centre through the node of Jupiter's orbit, the axis of y lying also in that orbit, and the axis of z being perpendicular thereto. Taking 4·5 seconds as the "probable" discrepancy between theory and observation for a single eclipse, the following preliminary estimates are obtained:—probable error in $a=43{\cdot}6$ km. per second; probable error in $b_1=45{\cdot}6$ km. per second; probable error in $c_1=10{,}000$ km. per second.

Royal Anthropological Institute, November 30.—Dr. A. C. Haddon, F.R.S., in the chair.—Canon **Greenwell** and the Rev. R. A. **Gatty**: Pit-dwellings at Holderness. An interesting discovery of pit-dwellings has been made by Mr. William Morfitt, of Atwick, near Hornsea, in Holderness. Mr. Morfitt for the past twenty years has devoted his attention to these dwellings, which are excavated 5 feet deep in the Boulder-clay, and are covered by an unbroken surface soil to the depth of 18 inches. The pits are filled with black mud, which on being removed discloses the original floor of the dwelling, with its hearth and broken pottery, the remains of past feasts in the form of broken bones, and the rude flint tools of the dwellers, for no well-shaped implement has come to light. About thirty of these dwellings have been examined and the pottery restored. Their great antiquity is proved by the fact that long after the inhabitants had ceased to occupy the pits, and mud had filled them up, a surface soil had formed to the depth of 18 inches, upon which late Neolithic implements and bronze implements have been found. This shows the dwellers to have been earlier than the Bronze age. The pottery is of the rudest kind, with no decoration. The bones remaining from the feasts include those of red deer, horse, Celtic ox, goat, and pig. Although the pits are now close to the sea, no fish bones or shells have been found in them, which proves that when they were occupied their position was far inland. The rapid demolition of the land by the sea in this part of Holderness accounts for this, but it also shows that a long period of time must have elapsed. In all probability these pit-dwellings are among the earliest habitations of Neolithic man which have been found in England. Prof. Boyd Dawkins was present when a fall of cliff had exposed one of these pits on the estate of Colonel Haworth Booth, and verified the fact that the surface soil covering the pit was unbroken, and must have been deposited after the pit had become filled with mud.

Faraday Society, November 30.—Mr. James Swinburne, F.R.S., president, in the chair.—Dr. H. J. H. **Sand**: The electroanalytical determination of lead as peroxide. This investigation was carried out with the object of elucidating the cause of the discrepancy between the statements of various experimenters regarding the behaviour of an electrolytic lead peroxide deposit on drying at 200°. All authors agree that the peroxide deposit retains water at this temperature, but whereas Hollard and Bertiaux give an analytical factor of 0·853, most other investigators find a factor of approximately 0·864, the theoretical factor being 0·866. Incidentally, the effect of varying conditions on the coherence of the deposit was also studied. It was found that at 200° a lead peroxide precipitate is capable of absorbing moisture from a damp atmosphere, and an increase of as much as 1·7 per cent. of the weight of the deposit has thus been obtained. On heating in a dry atmosphere at the same and higher temperatures the peroxide loses its water exceedingly slowly.—A. **Jaques**: The influence of dissolved gases on the electrode potential in the system of silver—silver acetate, aq. Variable values were found for the E.M.F. of the cell

$$\mathrm{Ag} \mid \mathrm{AgC_2H_3O_2}, x\mathrm{N} \mid \mathrm{NH_4NO_3}, \text{sat.} \mid 0{\cdot}1\ \text{N.E.},$$

and the variations were traced to the presence of dissolved air in the silver acetate solution. Measurements were made with saturated and 0·5 N silver acetate solutions saturated with hydrogen, oxygen, nitrogen, and carbon dioxide respectively, and reproducible values were obtained for the solution saturated with hydrogen which agreed with those calculated from the determinations of the E.P. of silver by G. N. Lewis and by Brislee. The values for solutions saturated with carbon dioxide also approximated to this. On blowing hydrogen into the solution saturated with carbon dioxide the potential fell about 30 millivolts, then gradually rose to about the normal value. With oxygen and nitrogen equal values were obtained—about 20 millivolts below that found with hydrogen. In 0·01 N silver acetate saturated with hydrogen the values were not reproducible. Similar measurements with 0·1 N silver nitrate and 0·5 mol. N lead acetate and lead nitrate showed that in these solutions the electrode potential is practically unaffected by the presence of dissolved gases.—A. **Jaques**: Contributions to the study of ionisation in aqueous solutions of lead acetate and cadmium acetate. From measurements of electrode potentials in solutions of lead and cadmium acetates, and their freezing points, and the solubility of silver acetate in them, it appears that in dilute single solutions ionisation occurs chiefly, though not entirely, according to the scheme

$$\mathrm{M(C_2H_3O_2)_2 \rightleftharpoons MC_2H_3O_2 + C_2H_3O'_2}$$
$$\mathrm{MC_2H_3O_2 \rightleftharpoons M^{\cdot\cdot} + C_2H_3O'_2},$$

where M represents Pb or Cd. Approximate values for the corresponding dissociation constants are calculated.—Prof. F. G. **Donnan** and Dr. G. D. **Hope**: The calorimetrical analysis of hydrated salts. The authors point out that the interpretation of the heats of solution of hydrated and partially dehydrated salt given by Thomsen in his "Thermochemische Untersuchungen" is in various cases either erroneous or unsatisfactory. It is shown that Thomsen's data for sodium carbonate indicate, when correctly interpreted, the existence of only the hydrates with 1, 7, and 10 mols. water per mol. anhydrous salt. The authors' experiments confirm this result. In the case of copper sulphate, neither the experiments of Thomsen nor those of the authors indicate more than the existence of the hydrates $\mathrm{CuSO_4{\cdot}5H_2O}$ and $\mathrm{CuSO_4.H_2O}$, though the hydrate $\mathrm{CuSO_4{\cdot}3H_2O}$ is known to exist.

Linnean Society, December 2.—Dr. D. H. Scott, F.R.S., president, in the chair.—Sir Charles **Eliot**: Nudibranchs from the Indian Ocean.—Dr. Georg **Ulmer**: Trichoptera von Mr. Hugh Scott auf den Seychellen gesammelt.—Dr. W. H. **Dall**: Report on the Brachiopoda obtained from the Indian Ocean by the *Sealark* Expedition, 1905.—Prof. J. S. **Gardiner** and others: Narrative of the *Sealark* Expedition, part iii.

Paris.

Academy of Sciences, November 29.—M. Bouchard in the chair.—L. **Maquenne** and M. **Demoussy**: The blackening of green leaves. The blackening of leaves by the ultra-violet rays is not due to a specific action of this radiation; it takes place equally under all influences which determine the death of the protoplasm, such as heat, chloroform, or mechanical rubbing. This phenomenon is a consequence of diastatic action, and falls into the same category as the facts observed for the first time by M. Guignard in his researches on the localisation of plant principles.—A. **Witz**: The regeneration of the exhaust gases from internal-combustion motors. The author suggests that the exhaust gases, taken from the cylinder without cooling, should be passed over a column of incandescent coke. The gas thus produced, containing carbon monoxide, is washed and re-admitted with pure oxygen to the gas-engine cylinder. It is assumed that the price of the oxygen, prepared from liquid air, is now sufficiently low for use in this manner commercially. The utilisation of the heat in the exhaust gases is calculated to give an economy of about 30 per cent.—S. **Arloing**: Antituberculous vaccination in the ox. An account of the practical results which have been obtained in the direction of obtaining immunity against tuberculosis in cattle in experiments which have been carried on for more than twenty-five years.—M. **Jarry-Desloges**: The period of rotation of Mercury. The surface of Mercury presents a certain number of dark spots, often well defined. The chief difficulty in perceiving these is the bad quality of the telescopic images. The rotation of Mercury from these observations would appear to occupy a long period, and is probably equal to the time of revolution.—Robert **Jonckheere**: Study of the planet Mars at the Observatory of Hem. Details are given of observations taken between July 16 and November 1 of this year.—Jean **Merlin**: Algebraical equations.—M. and Mme. Paul **Dienes**: Algebraico-logarithmic singularities.—Frédéric **Riesz**: Linear functional operations.—L. **Lichtenstein**: The determination of the integrals of the equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + a\frac{\partial u}{\partial x} + b\frac{\partial u}{\partial y} + cu = f.$$

—H. **Pellat**: The bifilar pendulum. A supplementary note to a recent paper on this subject dealing with the error introduced by the defective flexibility of the suspending metallic ribbons.—H. **Merczyng**: Studies on very short electromagnetic waves. Reflection and anomalous dispersion of liquids. These measurements necessitated the exact determination of the wave-length of the electromagnetic waves, and the method based on the dimensions of the vibrators not being sufficiently accurate, an interference method was worked out. The dielectric constants with these short waves (4·5 cm.) and the optical refractive indices were compared for several liquids, including glycerin, methyl and amyl alcohols, acetic acid, aniline, and ethyl ether.—Edm. **van Aubel**: The production of ozone under the influence of ultra-violet light. Experiments are described proving that ozone is formed by the rays from a quartz mercury lamp.—Laurent **Raybaud**: The destructive effect of the solar radiation. An account of the action of various radiations on cultures of *Phycomyces nitens*.—Georges **Meslin**: Magnetic dichroïsm and the orientation of crystals of siderose in the field.—Edmond **Bauer** and Marcel **Moulin**: The constant in Stefan's law. A possible source of error in the determination of this constant by M. Féry is pointed out, and the constant re-determined. The value $6{\cdot}0 \times 10^{-12}$ is considered to be correct within 1 per cent.—E. **Rengade**: The theoretical form of the cooling curves of binary mixtures: the case of mixed crystals.—Paul **Sacerdote**: Changes in the colour of the diamond under the action of various physical agents. The

X-rays do not sensibly modify the colour of the diamond, but considerable change is brought about by the action of the kathode rays, the diamond developing a yellow tint. This tint is permanent at the ordinary temperature, but an exposure to a temperature of 300° to 400° C. rapidly restores the original tint.—André **Meyère**: The influence of radium, the X-rays, and the kathode rays on various precious stones. The stones examined in these experiments were the diamond, and white, blue, and rose corundums. One effect only was produced by all three radiations—the stone became more or less tinted yellow.—J. B. **Senderens**: The catalytic preparation of unsymmetrical fatty ketones. Thoria is the most suitable catalyser for the purpose of these experiments, and is employed at a temperature of 400° to 430° C. A mixture of fatty acids passed over this reagent gives the ketone according to the equation

$$\mathrm{R.CO.OH+R'.CO.OH=R.CO.R'+CO_2+H_2O.}$$

Small quantities of the two symmetrical ketones are formed simultaneously, but the three ketones are readily separated by fractional distillation.—G. **Vavon**: Hydrogenations in the terpene series. Pinene rapidly absorbs hydrogen in the presence of platinum black, giving a nearly quantitative yield of the hydrocarbon $C_{10}H_{18}$. Camphene and limonene behave similarly. In alcoholic solution hydrogen can be added in this way to maleic, fumaric, and cinnamic acids, and to erucic acid in ethereal solution.—T. **Klobb**: The phytosterols from the flowers of *Tussilago farfara*. Two new alcohols are described, one being a monovalent phytosterol, the other divalent and resembling arnidiol in its behaviour.—Georges **Darzens**: The catalytic hydrogenation of the quinoline and aromatic bases. The exact temperature at which the nickel oxide is reduced, and the temperature at which the catalysis is carried out, are the two essential factors in the successful reduction of quinoline and aromatic bases. The preparation of tetrahydroquinoline is described.—Paul **Gaubert**: The polychroism of artificially coloured crystals.—H. A. **Brouwer**: Certain lujaurites from Pilandsberg, Transvaal.—Lucien **Daniel**: A new graft hybrid.—F. **Bordas** and M. **Touplain**: An anaëroxydase and a catalase in milk. Repeating some work of M. Sarthou, the authors come to the conclusion that the existence of an anaëroxydase and a catalase in cow's milk has not been demonstrated; the colour reactions produced in milk on treatment with hydrogen peroxide are due to casein or its compound with lime.—L. **Cuénot** and L. **Mercier**: Studies on the cancer of mice. Relation between the grafting of the tumour, gestation, and lactation.—C. **Levaditi** and K. **Landsteiner**: The transmission of infantile paralysis to the chimpanzee.—Jacques **Pellegrin**: A new parasitic fish of the genus Vandellia.—A. **Gruvel**: The dispersion of some species belonging to the marine fauna of the coasts of Mauritania.—Paul **Lemoine**: The subterranean folds of the Gault in the Paris basin.—André **Delebecque**: The origin of the plain of Rocailles (Haute Savoie).—M. **Répelin**: The *rôle* of the most recent dislocations (post-Miocene) in the earthquake of June 11, 1909.

DUBLIN.

Royal Irish Academy, November 8.—Dr. F. A. Tarleton, president, in the chair.—Dr. R. F. **Scharff**: The evidences of a former land-bridge between northern Europe and North America. The author explained that he was only dealing with the most recent land-bridge of which we had any evidence between the two continents. The testimony in favour of this theory is of a two-fold character. It is based on an investigation of the sea-floor and on a study of the plants and animals of the countries supposed to have been joined to one another by land. The author alluded principally to the continental shelves and to the researches of Prof. Hull, Dr. Spencer, and Dr. Nansen. He also brought forward botanical and zoological evidence pointing to the existence of a former continuous land surface between north-western Europe and eastern North America. The theory of accidental transport of species across the ocean was especially commented upon and discussed, but the author was inclined to adopt the view that the similarity between the fauna and flora of the two continents was mainly due to a pre-Glacial land-bridge connecting Scotland with the Færöes, Iceland, Greenland, and Labrador.

NEW SOUTH WALES.

Linnean Society, September 29.—Mr. C. Hedley, president, in the chair.—E. W. **Ferguson**: Revision of the Amycteridæ (Coleoptera), part i., the genus Psalidura. The family Amycteridæ comprises several groups of hard-shelled, apterous, and solely terrestrial weevils. The genus Psalidura comprises the group the distinguishing character of which is that the males possess anal forceps. The previously described species, numbering 37 in Masters's Catalogue, have been revised, and reduced to 24, to which number 22 new species are added, making a total of 46 species. Of these, it has not been possible to examine any specimens of four species, of which three—*P. D'urvillei*, *P. mirabunda*, and *P. squalida*—were described originally from female specimens only (and the descriptions are, therefore, almost valueless).—T. H. **Johnston**: The Entozoa of monotremes and Australian marsupials.—T. H. **Johnston** and Dr. J. B. **Cleland**: Notes on some parasitic Protozoa.—J. H. **Maiden** and E. **Betche**: Notes from the Botanic Gardens, No. 15, on a plant, in fruit, doubtfully referred to Cymodocea.

October 27.—Mr. C. Hedley, president, in the chair.—A. M. **Lea**: Revision of Australian Curculionidæ, subfam. Cryptorhynchides, part x. The tenth instalment of the revision continues the consideration of the genera allied to Chætectetorus, all of them belonging to the "Cryptorhynchides vrais" of Lacordaire. Twelve genera, and thirty-eight species, including fifteen proposed as new, are described.—A. F. B. **Hull**: The birds of Norfolk and Lord Howe Islands. The number of species actually known to breed at the present time amounts to twenty-nine for Norfolk and twenty-one for Lord Howe Island.—R. J. **Tillyard**: Studies in the life-histories of Odonata. No. 3. Notes on a new species of Phyllopetalia, with descriptions of nymph and imago. The species here named *Phyllopetalia patricia*, n.sp., was described by the author in 1906 under the name of *P. apollo*, Selys. Further investigation has shown it to be possessed of a number of important peculiarities, marking it out as a distinct species. The discovery of the nymph by Mr. Keith Brown at Leura, Blue Mountains, is of the greatest importance to ontogenists, as the specimen is the only known form of the Petalia group of dragon-flies. Evidence is brought forward, mainly on the form of the labium, strongly supporting the view advocated by Dr. F. Ris, that the Petalia group is not referable to the Cordulegasterinæ at all (though at present placed in that subfamily), but is an archaic remnant of the true Æschninæ.—Dr. H. I. **Jensen**: Notes on some recent work on the rocks of Samoa. Prof. M. Weber, of Munich, recently published an exhaustive report on the petrography of the Samoan Islands, based upon the examination of a very complete series of rocks collected by Herr J. Friedländer in 1907. Additional light is thrown upon two problems discussed in the author's two papers on the geology of Samoa, &c., in the Proceedings for 1906 (p. 164) and 1907 (p. 706), namely, the significance of the case of a recently erupted basalt which, on analysis, showed a higher soda content than was to be expected from the results of the petrological examination; and the bearing of the subalkaline composition of the Samoan lavas now established by Weber, upon the hypothesis that the eruptions along the Samoa-Tonga-Taupo line depend upon an earth-folding movement (*loc. cit.*, 1906, pp. 661–2).

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 9.

ROYAL SOCIETY, at 4.30.—The Hexosephosphate formed by Yeast-juice from Hexose and Phosphate: W. J. Young.—On the Presence of Hæm-agglutinins, Hæm-opsonins, and Hæmolysins in the Blood obtained from Infectious and Non-infectious Diseases in Man (Third Report): L. S. Dudgeon and H. A. F. Wilson.—Gametogenesis of the Gall-fly *Neuroterus lenticularis* (*Spathegaster baccarum*). Part I.: L. Doncaster.—Preliminary Note upon the Cell Lamination of the Cerebral Cortex of

Echidna, with an Enumeration of the Fibres in the Cranial Nerves: Dr. E. Schuster.—Cortical Lamination and Localisation in the Brain of the Marmoset: Dr. F. W. Mott, F.R.S., Dr. E. Schuster, and Prof. W. D. Halliburton, F.R.S.—The Caudal Fin of Fishes (Preliminary Paper): R. H. Whitehouse.—Some Experiments with the Venom of *Causus rhombeatus*: H. E. Arbuckle.—On the Comparative Action of Stovaine and Cocaine as measured by their Direct Effects upon the Contractivity of Isolated Muscle: Dr. V. H. Veley, F.R.S., and Dr. A. D. Waller, F.R.S.—*Glossina palpalis* as a Carrier of *Trypanosoma vivax* in Uganda: Colonel Sir David Bruce, C.B., F.R.S., Captains A. E. Hamerton and H. R. Bateman, R.A.M.C., and Captain F. P. Mackie, I.M.S.—A Critical Study of Spectral Series. Part I., The Alkalies, H and He: Prof. W. M. Hicks, F.R.S.—On the Distribution of the Röntgen Rays from a Focus Bulb: G. W. C. Kaye.—On the Nature of the Ionisation of a Molecule by an *a* Particle: R. D. Kleeman.—Conduction of Heat through Rarefied Gases: F. Soddy and A. J. Berry.—Harmonic Tidal Constants for Certain Chinese and New Zealand Ports: T. Wright.—The Photographic Action of the *α* Particles emitted from Radio-active Substances: S. Kinoshita.

Mathematical Society, at 5.30.—Exhibition of an Instrument for Solving Cubic Equations: T. H. Blakesley.—The Connection between the Theories of the Singularities of Surfaces and Double Refraction: A. B. Basset.—On the Representation of a Group of Finite Order as a Group of Linear Substitutions with Rational Coefficients: Prof. W. Burnside.—The Eliminant of the Equations of Four Quadric Surfaces: A. L. Dixon.

PALÆOZOIC STRATIGRAPHY.

Traité de Géologie. Vol. ii. Les Périodes géologiques. Fasc. i. By Prof. Émile Haug. Pp. 539–928. (Paris: A. Colin, 1908.) Price 9 francs.

THE first volume of Prof. Haug's treatise on geology was noticed in NATURE last year (vol. lxxviii., p. 123), and we now welcome the first part of the second volume, as it is as suggestive, and will no doubt be as useful, as its predecessor. The first volume deals with historical geology, and its first part describes the geological systems—of which the time equivalents are technically valued as periods—from the beginning of the geological record until the end of the Trias. The book continues Prof. Haug's valuable summaries of recent work, his judicious selection of new significant facts and figures, and it is rich in well-reproduced illustrations. It has the merit of being a very cheap text-book, as, though it includes 392 closely printed pages and twenty-eight excellent plates illustrating rocks, fossils and scenery, its published price is only 9 francs. A feature in the first volume that we remarked with regret was the scanty reference to British work; this volume is a great improvement in that respect, as British geology receives its fair share of attention, though the author must have missed several important recent memoirs or he would not have remarked that Carboniferous palæontology has been for a long time past neglected in this country or inserted the footnote on p. 763. The author does not always select for reference the most valued British results, for he quotes Monian and Arvonian, and omits some later more useful terms.

The Palæozoic he divides into four systems—Cambrian, Silurian, Devonian, and Anthracolitic. He subdivides the Silurian into two subperiods, the Ordovician and Gothlandian, and as he admits that they are independent, both stratigraphically and palæontologically, it may be regretted that he does not accept them as distinct systems; for if the name Gothlandian continues to increase in favour, there is a danger that when the two divisions are accepted as separate systems, the term Silurian will fall altogether into disuse. The Devonian system the author adopts mainly on stratigraphical grounds, as he remarks that the fauna alone is insufficient to justify the distinction, as it is so poor in families special to the period.

The volume begins with an introduction to the principles of stratigraphy, and then describes the geological periods in turn. Prof. Haug explains the gradual recognition of the scientific basis and world-wide value of the divisions between the geological systems, for they are due to movements which affected the world as a whole, and by modifying geography and climate produced simultaneous changes in the contemporary faunas and floras. In his account of each system he begins with the history of its classification and nomenclature; he then gives a list of characteristic genera and some notes on the life of the period, illustrated by numerous well-selected figures, such as Ruedemann's Siphonophora-like colony of graptolites with its float. Then follows a brief summary of the distribution of the system through the world, with especial reference to the types of sediments and the relation of the rocks to the transgressions and retreats of the sea. Finally, he gives a sketch of the climate, zoological provinces, and distribution of ocean and continent in the period.

Prof. Haug divides pre-Cambrian time into only two periods, the Archæan and Algonkian. The term Archæan he uses in the sense defined by its founder Dana; he does not go with those—an increasing number—who subdivide the Archæan into two groups, a lower for the massive basal rocks and an upper for the pre-Algonkian schists. The Algonkian he accepts for the comparatively unaltered pre-Cambrian sediments, such as our Torridon sandstone.

One unorthodox feature in the author's classification is his acceptance of one system, for which he adopts Waagen's name Anthracolitic, to include both the Carboniferous and Permian. The suggestion to unite them has been so often made that it is clear that the evidence on its behalf is weighty. It is true that the invertebrate fauna of the Permian is not by itself sufficient to characterise a special geological system, but the great geographical changes and the important development of the vertebrates are strong arguments in favour of maintaining the Permian as a system. The author practically describes the Carboniferous and Permian apart, and together they would make a system inconveniently large and varied.

In the names of the series into which the systems are divided Prof. Haug attaches great weight to priority; thus he rejects the Mississippian of Prof. H. S. Williams because the name had been employed before in a different sense by Marcou, and he appears to regret that he cannot adopt Missourian, instead of the less convenient Uralian, on the ground that the latter is a year older. But as the author rejects Bernician, owing to its having been less adequately defined than the later term Dinantian of de Lapparent, he fortunately allows some discretion in the selection of names. He, however, appears disposed, as a stratigrapher, to pick up the heavy burden of priority which palæontologists are now preparing to throw off.

The account of each geological system concludes with a sketch of its climate, biological provinces, and geography, and the author's work shows the rapid growth in our knowledge of these interesting sections of the earth's history. He directs attention to the numerous Palæozoic glaciations, now proved, including the Huronian described by Coleman at Cobalt, in Canada, the Cambrian discovered by Howchin in South Australia and by Bailey Willis in central China, the Devonian found at Cape Town by Rogers, and the long-known Upper Palæozoic glacials of India, South Africa, and Australia. He rejects the explanation of the last as due to the shift of the South Pole into the Indian Ocean, and attributes the glaciations that occurred in at least four areas of Gondwanaland to geographical causes. He notices the indications of various Palæozoic deserts, but does not mention the desert theory in connection with the origin of the Old Red Sandstone, which he attributes to formation in a lagoon or in a sea like the Baltic, which had some slight connection with the open ocean. His maps of the distribution of land and water in successive systems are excellent diagrammatic sketches, and those of Europe give the chief facts of its complex history. Prof. Haug is an expert on the geological history of France, and he clearly explains the many important differences between the Armorican region and the Central Plateau; he shows these two areas by different hachures in three out of his four structural maps of Europe, and it is only in that of the Gothlandian (Silurian) that the two regions are shown as sharing the same geological conditions. J. W. G.

SYSTEMATIC BOTANY.

(1) *Illustrations of Cyperaceae.* Prepared under the direction of the late Charles Baron Clarke, F.R.S. 144 plates, with explanation. (London: Williams and Norgate, 1909.) Price 12*s.* 6*d.* net.

(2) *Das Pflanzenreich. Regni Vegetabilis Conspectus.* Edited by A. Engler. 38 Heft, iv, 20. *Cyperaceae-Caricoideae.* By Georg Kükenthal. Pp. 824. (Leipzig: W. Engelmann, 1909.) Price 41.20 marks.

(3) *Das Pflanzenreich. Regni Vegetabilis Conspectus.* Edited by A. Engler. 39 Heft, iv, 83. *Phytolaccaceae.* By Hans Walter. Pp. 154. (Leipzig: W. Engelmann, 1909.) Price 7.80 marks.

(1) "WE hope, Mr Clarke, that you will live a very long time!" Mr. C. B. Clarke was fond of quoting this remark make to him by a well-known botanist, Mr. Henri Baillon, if we remember aright, who appreciated his careful work on the Cyperaceæ, a difficult family of plants, and one of which a good monograph was much needed. Unfortunately, Mr. Clarke did not live to complete the monograph to which he devoted so much time during the last twenty-five years of his life, and in connection with the preparation of which he had visited, or received plants from, most of the important botanical collections. The work was left in manuscript which proved too extensive for immediate publication, and botanists must for the present be satisfied with excerpts of the descriptions of new genera and species, together with a skeleton of the author's arrangement, which have been published in the Kew Bulletin (Additional Series, viii.). For particulars of synonymy and details of geographical distribution, reference must be made to the manuscript which is preserved at Kew. It is to be regretted that it was found impracticable to render accessible by means of publication the full results of the work of so close and careful a student of so difficult a family. It is true, as Mr. Clarke himself was wont to observe when reproached with delay, that much of the work had already been published in the important floras of various parts of the world in connection with which he was invariably laid under contribution for the elaboration of the Cyperaceæ; such, for example, as the "Flora of British India," the "Flora of Tropical Africa," and others; but the *magnum opus* which should correlate the parts and supply a complete account of the family is wanting.

The volume now under review comprises a series of 144 plates prepared by Mr. Clarke to illustrate the monograph, many years ago, when the plan of arrangement had been determined, as well as the representative and typical species of each genus. They have been drawn by various artists—Mr. N. E. Brown, Mr. Charles Fitch, and Miss M. Smith; most have been reproduced by the collotype process, but some by lithography. They are remarkably clear. A characteristic feature is the representation on a large scale of dissections of the spikelets and flowers, with diagrams illustrating arrangement of parts, and enlargements of the fruit—an important diagnostic character in the Cyperaceæ. Facing each plate is an explanatory page of text indicating in many cases the actual specimen from which the drawings were made, such as R. Brown, n. 6020; Burchell, n. 7892. The whole forms an invaluable series of detailed drawings illustrating the floral morphology of the genera and species of Cyperaceæ. Dr. B. D. Jackson, who is responsible for the production of the volume, refers in his preface to the generosity of Miss Clarke, the sister of the author, to which the issue of the plates is due.

(2) Georg Kükenthal has the reputation of a careful worker on the section of Cyperaceæ, a systematic account of which is embodied in this ponderous Heft of the *Pflanzenreich*—the most substantial from the point of view of size that has yet appeared. In the general account which precedes the special descriptive portion, the author refers to the division of the order into subfamilies based on the presumed cymose character of the spike in many of the genera; two subfamilies were at first recognised—Scirpoideæ, with racemose spikelets, and Caricoideæ, in which the spikelets were of a cymose nature. Subsequently, however, the author was led to restrict the Caricoideæ to Carex and a few allied genera, and it is in this restricted sense that the term is employed in the present monograph. As thus limited, the subfamily contains four genera—Schœnoxiphium, a small South African genus of six species, one of which is also represented on the highlands of east tropical Africa; Cobresia, for which the author prefers the more correct to the more familiar spelling, Kobresia (the genus was named by Willdenow in honour of Paul de Cobres); Uncinia, and the huge genus Carex. The author follows Mr. Clarke in including Elyna and Hemicarex in Cobresia, and arranges the twenty-eight species in the four sections suggested by Mr. Clarke. The chief interest of the book, however, is naturally centred in the exhaustive systematic revision of Carex, of which just upon 800 species are recognised. A true estimate of the value of Kükenthal's work on this genus can only be ascertained by experience in its use in the field and in the herbarium; but it is at any rate a great thing to have a carefully elaborated monograph with full specific descriptions and detailed accounts of synonymy and geographical distribution. We have long waited for a successor to Boeckeler's monograph for purposes of arrangement of the species.

(3) The systematic treatment of the order Phytolaccaceæ, by Hans Walter, differs but slightly from that adopted by Bentham and Hooker in the "Genera Plantarum." The three tribes into which the order is there divided—Rivineæ, Euphytolacceæ and Gyrostemoneæ—are here maintained with almost identical limitations. Bentham's genus Stegnosperma, classed in the "Genera Plantarum" as a *genus anomalum*, is regarded by Walter as the type of a distinct subfamily, the order being divided into two subfamilies—Phytolaccoideæ and Stegnospermoideæ, the latter containing the single genus Stegnosperma. There has been considerable difference of opinion as to the limitation of this order, especially in relation to the Ficoideæ, certain genera having been included by different authors in each family. The criterion of one or more than one ovule in the carpel is not a universal one, and the author of the present monograph is convinced that the structure of the inflorescence forms a better means of distinction between the two families. A good proportion of new species is described in the course of the work; thus, of twenty-six species of Phytolacca, seven are here described for the first time.

A. B. R.

THE HAND-LIST OF BIRDS.

A Hand-list of the Genera and Species of Birds. (Nomenclator Avium tum Fossilium tum Viventium.) By R. Bowdler Sharpe. Vol. v. Pp. xx+694. (London: British Museum, Natural History, 1909.) Price 20s.

DR. SHARPE may be assured not only of our own congratulations, but of those of ornithologists in general, on the completion of his heavy task and the issue of the final volume of a work the first of which appeared so long ago as 1899. No one who has not tried it can have any conception of the enormous amount of labour involved in a task of this nature, and when we add that the author estimates the total number of distinguishable forms of birds as close upon 19,000, it will be unnecessary further to emphasise the magnitude of the work just brought to a close.

The value of these five volumes to the working ornithologist—whether we altogether agree or not with the author's view as to the limitations of genera, the multiplication of family groups, and the non-recognition of local races—can scarcely be overestimated, although it must always be borne in mind that the work is meant to be used in connection with the British Museum Catalogue of Birds, to the volumes of which references are given under the headings of the various species. In the case of many species, one or two synonyms are given; and almost the only improvement that we could suggest is that in the case of genera and species where well known names have been changed it would have been better if a larger number of synonyms had been quoted, which could have been done without any increase in the bulk of the volume, as there is a large amount of blank paper.

We are glad to see that in the introduction Dr. Sharpe takes the opportunity of making certain amendments in the arrangement of the "orders" of birds, such emendations being, in our opinion, for the most part a decided improvement on his previous scheme. The most important item in this remodelling is the abolition of Carinatæ and Ratitæ as the two main divisions of existing birds, and the inclusion of the tinamus with the ostriches to form one group distinguished by the structure of the palate from a second group containing all other existing birds. When, however, the author proposes to regard these two groups (Neognathæ and Palæognathæ) as equivalent in rank to the one (Saururæ) containing Archæopteryx, we beg to dissent from his views.

In our notices of at least one of the previous volumes of the "Hand-list" we have directed attention to the want of uniformity in the spelling of geographical names. Unfortunately, the author has not availed himself of the hint, with the result that the "pleasing" variety of orthography is more pronounced in the present issue than in any of its predecessors. We have, for instance, Malay Peninsula and Malayan Peninsula on the some page (62), and Malacca in another place; Dentrecasteaux (p. 63) and D'Entrecasteaux (p. 69); Niasa-land (p. 47), Nyasaland (p. 35), and Nyasa Land (p. 474); Cashmere (p. 167) and Kashmir (p. 173); Szechuen (p. 233) and Szechuan (p. 268); Somali-land (p. 184) and Somali Land (p. 465); Damara-land (p. 185) and Damara Land (p. 475); and Island of St. Thomas in one place (p. 463) and S. Thomè Isl. in another (p. 635). We may also note (p. 175) Lipikia for Likipia. In our own experience, the only way to avoid discrepancies of the above nature is to enter every name as it occurs in a list, and to check all subsequent occurrences. With the exception of these discrepancies, which are creditable neither to the author nor to the museum, we have little except commendation to bestow on the volume before us.

For reference purposes, the whole work suffers, however, from the circumstance that the page-headings on both sides are taken up by useless repetitions of the general title, whereas the heading on one side should have carried the family-names. In the case of large families, to find the family-position of a genus it is necessary, after ascertaining the page on which it occurs from the index, to turn back until the family-name is reached, or to refer to the table of contents. In this respect the work compares badly with the "Catalogue of Birds' Eggs." A general index to the five volumes would also have been very useful.

R. L.

SOCIAL EVOLUTION.

Darwinism and Modern Socialism. By F. W. Headley. Pp. xv+342. (London: Methuen and Co., 1909.) Price 5s. net.

MR. HEADLEY has given the general reader a comprehensive and well-stated case against Socialism. He brings together the best of the known economic arguments, and bases the whole on biological principles.

The text is that "it is very difficult for a follower of Darwin and Weismann to be a Socialist." In a survey of early forms of mutual dependence, such as the village community in England and India and the Russian *mir*, he shows that the Socialism, so-called, of the primitive and pre-industrial epochs did not conflict with Darwinian principles. The new Socialism, however, aims at stopping "the struggle for existence" and the elimination of "the unfit."

Much stress is laid all through on the institution of the family, which is a permanent possibility of individualism, and the eternal matrix of capitalism.

The author's view is clear; he avoids irrelevancy, and has the faculty of going straight for the point and of illustrating it by well-chosen examples. Thus he shows that "natural selection" acts only at crises, such as disease or war. In an excellent analysis of the work of our Post Office he emphasises the only relevant points, namely, that all Government departments are wasteful, and that success is really the result of "private" enterprise and of "private" criticism. The same truths apply to "the common sense of municipal trading," a curious hybrid between Socialism and Capitalism. The proofs of all this are well put.

"To abolish private industry would be to kill the goose that lays the golden eggs"; and this is what the Socialist proposes to do. The two chapters which demonstrate this are excellent, and the author has humour as well as insight.

The main defect of our economic system (to which is ascribed the vigour of theoretical Socialism) is excessive accumulation of capital. The main duty of the State is to act as umpire in the competitive struggle. It must not itself produce.

As to minor points calling for criticism, the explanation of the custom of a mock "capture" of the bride as a survival of "bride-lifting" from another tribe is obsolete. Such ceremonies have a psychological origin. The bride is "captured" from her sex and herself.

The frequent objection of Socialists to Christianity is hardly due to a desire to abolish the family. It is rather due to its claim of "authority" and its tendency to Erastianism.

Yet about this book, as about previous applications of "natural selection" to human society, there is something unsatisfactory. False analogy and ambiguity of terms may result, if we forget the fact that in a civilised community survival largely depends on factors which do not exist in "nature."

This doubt may be applied by the reader to chapter ix., the most crucial and the least convincing. It is on "natural selection among civilised peoples."

There is something wrong about the identification of the struggle for existence in the natural world with our competitive system. Transfer a typical unemployed to a state of nature and he would survive. The conditions of the two cases are so different.

Then what is survival-merit now? Mr. Headley speaks of steadiness, honesty, and thrift. An impartial view must add unscrupulousness, low cunning, incapacity for generosity, mercy, and the nobler ideals, for art and culture, and—for conscientious work. Moral values are, of course, a matter of time and place, but there is such a thing as dehumanisation. Add physical survival-merit, and consider if we are not evolving a type which has been described as "a race of men, small, ill-formed, disease-stricken, hard to kill."

He speaks of our lowest class as living in a "primitive" fashion. By its "best blood" the next stratum is reinvigorated. Here is ambiguity of terms.

The selection going on under our competitive system is not necessarily producing "the splendid pattern" of which Mr. Headley and the poet have dreamt.

A. E. CRAWLEY.

A HERO OF MEDICINE.

Semmelweis: his Life and Doctrine. By Sir William J. Sinclair. Pp. x+369. (Manchester: University Press, 1909.) Price 7*s.* 6*d.* net.

"IN the history of midwifery there is a dark page, and it is headed Semmelweis." Semmelweis was a prophet, and he was misunderstood by the people he came to save. The services he rendered mankind cannot be overestimated. His discovery was epoch-making. He established the cause of puerperal fever, and threw light on all septic conditions. Before his time the cause of wound infection was not understood. Semmelweis proved that puerperal fever was analogous to wound fever, both being due to contamination from putrid organic matter. The cause of puerperal fever having been established, Semmelweis worked at its prophylaxis. He insisted on the cleanliness of the patient and her surroundings, and sketched the principles which underlie the antiseptic and aseptic treatment of wounds, and so laid the foundation for modern surgery, gynæcology, and obstetrics. During his life Semmelweis was misunderstood and misrepresented; he met with opposition, jealousy, and hatred from his own profession; he was degraded and belittled; yet, to-day, his conclusions are universally accepted and form the foundation of surgical thought.

There should be a wide public, lay as well as medical, for a book as full of historical, scientific and human interest as this "Life of Semmelweis." It is a just tribute to the memory of a very great man. The only criticism which might be made is that the last hundred pages, dealing with discredited contemporary opinions, might have been curtailed. The early chapters give a vivid account of the conditions under which Semmelweis worked as student and assistant in the great lying-in hospital of Vienna. His attention was soon arrested and his heart wrung by the appalling death-rate among the patients, and he resolved to find the cause of the scourge which decimated the hospital. Broadly, the facts were these: the mortality among women delivered in the hospital, always higher than that among those confined at home, suddenly rose to an unprecedented figure in the year 1822, when the anatomical basis of instruction was introduced into the curriculum of the medical students. The students used to pass from the dissecting-room to the labour wards, and from this time the hospital mortality rose until at one period nearly half the patients died. The lying-in hospital consisted of two divisions similar in every respect, except that in the first division the women were attended by the students and in the second division by midwives. Semmelweis found, over a period of five years, that the mortality in the first division remained three times as high as that in the second. What was the cause of this? A significant entry occurs in his note-book:—"All is doubt and difficulty. Only the great number of the dead is an undoubted reality."

In 1847 Semmelweis's friend Prof. Kolletschka died of septicæmia from a scratch on the finger received at a *post-mortem* examination. The circumstances of this tragedy, its origin from the introduction of a poison into a wound surface, the course of the illness, and the pathological results revealed by examination of the body after death brought illumination to Semmelweis. This was a similar condition to the "fever" of puerperal women; both were due to inoculation of putrid organic matter, hence the terrible mortality among women attended by students fresh from the mortuary and the better results obtained by the midwives. In 1847 "the eternally true doctrine" was announced, but no wide publicity was given to it, and it failed to obtain general acceptance. Had Semmelweis been a ready speaker or writer, had his personality been different, more ambitious, perhaps even more winning, the great truth might have been accepted by the profession. Instead of this he died unrecognised, after years of embittering and acrimonious discussion. Sir William Sinclair's book is of the greatest interest, and we are glad to welcome an adequate English appreciation of Semmelweis, who certainly ranks among the "heroes of medicine."

NON-EUCLIDEAN GEOMETRY.

The Elements of Non-Euclidean Geometry. By Dr. J. L. Coolidge. Pp. 292. (Oxford: Clarendon Press, 1909.) Price 15*s.* net.

THIS work will be found really valuable by all students of geometry, especially by those who know little or nothing of the non-Euclidean theories. First of all we have a discussion of the elementary axioms; in this the plane is deduced from what may be called a triangular frame, in the manner of Peano and Schur. Then comes the discrimination of the three cases, according as the sum of the angles of a plane triangle is equal to, greater than, or less than two right angles; and this is followed by the fundamental trigonometric formulæ for a triangle, deduced very neatly from Saccheri's isosceles birectangular quadrilateral. It is also proved at this stage that the non-Euclidean plane can be developed upon a surface of constant curvature in Euclidean space.

The author next proceeds to a discussion of higher spaces (in three dimensions), the absolute, and groups of congruent transformations. The treatment here is entirely analytical, and for the beginner, at any rate, this is doubtless the proper course to take. In fact, most will feel that the analytical treatment of the subject has the great advantage of preserving us from fallacies and vicious circles.

The next chapters contain developments relating to curves and surfaces of the first and second orders; in particular, there is an interesting chapter on the higher line-geometry. In some respects this is analogous to Staudt's representation of an imaginary line of the second kind; but it should be said that there is only a very brief sketch (pp. 127–30) of the interpretation of imaginary coordinates in non-Euclidean space.

The chapter on areas and volumes is remarkably good and clear. The formula for the area of a triangle is obtained by a method which is both elementary and rigorous; and there is a very interesting discussion of the volume of a tetrahedron.

Chapters xv. and xvi. are on differential geometry, and here again the treatment is admirable. For one thing, the quantities usually denoted by D, D', D'' present themselves in a natural way instead of resulting from a long and tedious calculation. Among the prettiest results of these chapters are the extensions of Meunier's theorem and of Gauss's theorem on the total curvature at any point on a surface.

There is a brief discussion of multiply connected spaces, and two final chapters, each of which is, in fact, an independent presentation of the subject, one from the projective point of view, and the other, like that of Riemann's famous essay, based on the properties of a quadratic differential form. The reader cannot fail to profit from these various ways of regarding the subject; their agreement in results will help to free him from the natural prejudice which many entertain—that non-Euclidean geometry is a mere juggling with symbols, having no relation to the properties of space as it actually is. After the recent critical work on the foundations of geometry, the conclusion is inevitable that there are no grounds at present, and probably never will be, for asserting that the space of physical phenomena is Euclidean or non-Euclidean; while in the realm of speculation the three kinds of space are coordinate, and equally possible.

G. B. M.

COLOUR PHOTOGRAPHY.

Über Farbenphotographie und verwandte naturwissenschaftliche Fragen. By Prof. Otto Wiener. Pp. 88. (Leipzig: J. A. Barth, 1909.) Price 2.40 marks.

THERE is, perhaps, no more remarkable recent scientific achievement than the realisation of the problem of photography in colours, which has occupied the thoughts and aspirations of many workers since the day when Nicéphore Niépce, the founder of photography, told the Marquis de Jouffroy that one day he would reproduce his likeness just as he saw it in a mirror.

In this reprint of a discourse on colour photography and kindred physiological questions, delivered at the Congress of Naturalists in Cologne in September, 1908, Dr. Otto Wiener has given a brief sketch of the principles of the various methods of colour photography, with additions, chiefly of omissions from the discourse itself, together with copious notes and references to the literature, and further details of the subject, and the biological side of the question as regards colour mimicry in animals. It is illustrated with three plates in colours.

The author first discusses the nature of white light, its decomposition and recomposition, the nature of the colours shown by coloured objects, pigments, dyes, &c., and their effects on the reflection, absorption, and transmission of white light, with special reference to the coloured glasses to be used as filters in three-colour photography. Then the various processes by Ducos du Hauron, Ives, Sanger Shepherd, Joly, Miethe, Lumière, and others for producing coloured photographs by the additive and subtractive methods of colour mixtures, dependent on the theory of triple-colour sensations enounced by Young, Helmholtz, and Clerk Maxwell.

The discussion of the Becquerel and Lippmann direct methods of colour photography, founded on Zenker's theory (1868) of interference and stationary waves producing an alteration of the structure of the sensitive film by reflection, corresponding to the wavelength of the light acting on it, is interesting, because of the author's confirmation of the theory in 1890, and its practical adaptation by Lippmann in 1891. The other direct methods, dependent on changes of colour in sensitive films of silver chloride and subchloride, discovered by Seebeck and worked out by Becquerel, Poitevin, and Niépce de St. Victor, also the "bleach-out" methods of Worel, Neuhauss, Smith, and others are explained. After a short notice of the theories of colour perception, the discourse concludes with some very interesting remarks regarding the protective colour adaptation of animals, and the researches of Poulton, Standfüss, Weismann, Herbert Spencer, and others, illustrated by a coloured plate showing protective mimicry in insects.

Though the subject is dealt with briefly and theoretically, the book will be useful as a summary of results already achieved, and particularly for the literary and other information given in the notes. We note one omission in the list of books at p. 49—Dr. H. W. Vogel's "Die Photographie farbige Gegenstände," 1885. Those interested will find further information in Prof. Wiener's papers in *Wiedemann's Annalen*, xxxi., 1887, p. 619; xl., 1890, p. 203; lv., 1895, p. 225; and Eder's "Jahrbuch für Photographie," 1896, p. 55.

J. W.

OUR BOOK SHELF.

Outlines of Chemistry, with Practical Work. By Dr. H. J. H. Fenton, F.R.S. First part. Pp. xvi + 365. (Cambridge: The University Press, 1909.) Price 9*s.* net.

THIS book embodies the substance of a course, or part of a course, of lectures which the author gives to candidates for the Natural Science Tripos at Cambridge. Supplemented in practice by experiments appropriate to the topics of each lecture, it is intended to give the student a lead to the study of standard chemical literature. Mr. Fenton explains the difficulty of the circumstances under which the teaching has to be done, and he appears rather as one who has to comply with an established system than the exponent of a system that he thinks the best, or even very good. No one, of any modesty, who is engaged in teaching chemistry to university students at the present day will be very dogmatic about the details of the course that should be followed. The subject has become so vast and so varied that personal predilections and capacities may lead to courses very different from one another and yet of no very different merit. Two extremes may be found in the tendency of one kind of teacher to produce a chemist well informed about substances and another kind to produce a chemist well informed about principles; the first would ordinarily be the better craftsman, the second the clearer thinker.

The tendency of the Cambridge Tripos system is not unnaturally towards making chemistry as much like physics as possible, and accordingly the Tripos candidates are led to concern themselves with theoretical and physical chemistry to an extent which seriously limits their chances of acquiring that personal familiarity and facility with individual chemical substances which in earlier days was one good outcome of the *régime* of analysis. It leads also to a subordination of chemistry in relation to industrial and practical problems. It is possible that some readjustment might be worth considering, having regard to the increasing importance of the Cambridge school and especially to the influence which Cambridge graduates exercise in the secondary schools.

However this may be, Mr. Fenton, on the lines he had adopted, has written a book that must be rated very highly. It is marked throughout by the lucidity and scientific restraint to which we have been accustomed in all his writings; it is very thorough and comprehensive, and it shows a real grasp of the inwardness of a good many things about which there has been a good deal of loose writing and, presumably, loose thinking. It is a book that may be read with profit by every student of chemistry at some stage of his career—perhaps for most at some late stage, when reviews are so valuable, especially if they are free from special pleading. As an example of the excellent substance and form of the book, the chapters on acids, bases and salts may be specially cited, but there is, in fact, little departure from a high level of exposition throughout the work. It seems very likely that the second volume, which is promised, should the first prove acceptable, will be clearly called for.

A. SMITHELLS.

The Kea: a New Zealand Problem. By G. R. Marriner. Pp. 151. (London: Williams and Norgate, 1909.) Price 7*s.* 6*d.* net.

FEW birds have attained to greater notoriety than the New Zealand kea, and every naturalist has long been familiar with the strange story of its sheep-killing propensities. The change of habit which it is supposed to have undergone since the introduction of sheep into New Zealand has formed the subject of much discussion by writers on evolution, but it appears that a great deal of theorising has been based upon a singularly small amount of trustworthy evidence. Serious doubt having been cast upon the generally accepted stories, Mr. G. R. Marriner, the curator of the public museum at Wanganui, set himself the task of collecting all the evidence available and personally investigating the habits of this remarkable bird, and the results of his inquiry have been published in a very valuable and readable book. The case has been fairly tried, and the kea stands condemned on abundant evidence. The executioners have long been at work. They did not think it necessary to wait for the result of the trial, and the large sums of blood-money paid for kea heads must have done a good deal to keep the birds in check, though their haunts in the remote mountain regions of the South Island are often so inaccessible that it may well be doubted whether they will ever be exterminated. Those who love bird-life better than mutton will probably hope not.

The natural food of this extraordinary parrot consists of fruits, roots, honey, worms, insects, and grubs. It is gifted with an inordinate curiosity, and seems ever ready to experiment and investigate novelties. Mr. Marriner believes that this inquiring spirit is responsible for its predilection for fresh meat; that it first began by experimenting with sheepskins and dead carcases, and later on took to killing on its own account. The idea that the kidneys are its especial tit-bits seems to be based entirely upon the fact that the sheep is generally attacked in their neighbourhood; this, however, is the only part upon which the kea can maintain a footing while the sheep is racing about and trying to throw off its torturer. The cruelty of the whole proceeding is horrible in the extreme, and the annual loss to the run-holders is estimated by the author at 5 per cent. of the flocks. The birds appear to enjoy their sport exceedingly, but they have not yet learnt wisdom, and fall an easy prey to the avenger. When the kea hunter has exhausted his cartridges, he sometimes, we are told, allows the birds to see him disappear behind an overhanging ledge of rock. Their curiosity induces them to try and find out what has become of him, and one by one they walk to the edge and look over, only to be knocked on the head by his stick. If so, why waste cartridges? Perhaps there is not always a suitable rock handy.

The book is brightly written, and contains some good illustrations, and we recommend it to all lovers of nature. Considering its size, however, the price seems to be rather high. A. D.

(1) *How to Study the Stars.* By L. Rudaux; translated by Dr. A. H. Keane. Pp. 360. (London: T. Fisher Unwin, 1909.) Price 5*s.* net.

(2) *How to Identify the Stars.* By Dr. Willis I. Milham. Pp. v+38+plates. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1909.) Price 3*s.* net.

(1) Both the means and methods of observation dealt with in this book are eminently practical, being founded for the greater part on the progressive astronomical equipment of the author and the methods which, in actual use, he has found effective. The needs of the amateur are all along kept in mind. The interested and intelligent user of a pair of opera glasses is led to make for himself apparatus more ambitious. As the possessor of a telescope he is shown practical, and often home-made, mountings for the smaller sizes, while for the amateur of means, to whom a medium-sized equatorial reflector or refractor is possible, the question of a suitable house for his instrument is dealt with. Here the varied experience of the author is called in, the important question of cost not being forgotten.

Part ii. is concerned mainly with methods of observation and results. The study of sun, moon, and planets is undertaken, often with apparatus by no means extravagant, and the kind of results which may be expected are indicated, by reference to the author's own work, and by actual photographs reproduced.

For the purpose of progressively instructing amateur astronomers, the book should prove successful. The translation seems, on the whole, well done, and a readable work has been produced.

(2) The title of this book suggests at once its elementary nature. The appeal both of the text and the charts is to beginners in astronomy. The thirty-eight pages of letterpress deal in a sketchy way with such subjects as the history of the constellations, stellar magnitudes, and colours and methods of study. So many subjects in so few pages obviously precludes any fulness of treatment. The "history" consists chiefly of a list of constellation names, with genitives and meanings, together with the names of their proposers, and the section devoted to "star colours" occupies less than a page. The list of the twenty brightest stars, giving magnitudes and colours, is useful, while the division of the eighty-eight constellations into four distinctive groups should prove helpful in memorising.

Four small charts, showing the stars visible at convenient hours during the various months of the year, and twenty-four constellation tracings are appended.

An excellent feature of the publication is the list, at the end of each section, of books and papers suggested for further study.

The general method followed and material presented is stated to be essentially the same as that used in the course on descriptive astronomy in Williams College. Within its limitations the work is accurate and serviceable, and may be recommended as a convenient epitome of the subject.

Scientific Nutrition Simplified. By Goodwin Brown With a Supplementary Chapter by Dr. J. Sven. Pp. xi+271. (London: William Heinemann, 1909.) Price 2*s.* 6*d.* net.

This little book is one of the simple-life series. It puts in popular language the information for the practical application of the principles of nutrition advanced by Mr. Horace Fletcher and Prof. Chittenden. The main principle involved is the reduction of the protein intake to about half the amount usually accepted by physiologists as the normal. In reviews of similar books which the present writer has contributed to Nature during the last few years, it has been pointed out that the Chittenden *régime* is not free from danger, and it is unnecessary to traverse the same ground again. The general tenor of the present work contrasts very forcibly with the scientific exposition of the subject in the work of Max Rubner recently reviewed (November 4, p. 2). The enthusiast sees only the *pros* and does not pause to consider the *cons.* in a subject which really bristles with difficulties. No one wishes to advocate over-eating, but to preach a doctrine of under-feeding as a permanent and universal practice is a very different thing from the temperance and moderation which is the ideal. The majority of physiologists have condemned the Chittenden diet as insufficient, and those with knowledge are more likely to be correct than the faddists, even if they can count one or two disciples drawn from the scientific world in their ranks.

A great point is made in the present work of Mr. Fletcher's advocacy of thorough mastication. Nobody denies the importance of the saliva and of the process of chewing, but to advocate the supreme importance of the least important of the digestive juices, and to elevate the action of the jaws into what seems to be regarded almost as a religious exercise, is not only unscientific, but ridiculous. W. D. H.

A Barometer Manual for the Use of Seamen; with an Appendix on the Thermometer, Hygrometer, and Hydrometer. Issued by the authority of the Meteorological Committee. Sixth edition, extensively revised. Pp. 67. (London: H.M. Stationery Office, 1909.) Price 3*d.*

Although chiefly intended for the use of seamen, this manual will be found of much service by anyone desirous of obtaining accurate information relating to the use of the barometer, and its connection with weather conditions and storms experienced in all parts of the globe. It is a revised edition of the Barometer Manual prepared by the late Admiral FitzRoy, formerly chief of the Meteorological Department of the Board of Trade, which was very favourably received. The popularity of the present manual and its immediate precursors has been greatly increased by its adoption by the Board of Trade as a text-book in connection with the examination of masters and mates in the mercantile marine service. It has been prepared under the superintendence of Commander Hepworth, marine superintendent of the Meteorological Office, formerly a keen observer of meteorological phenomena in various oceans. Several new charts have been constructed from the materials in the possession of the meteorological committee, and show, *inter alia*, the mean isobars for the middle months of each quarter, and the pressure and prevailing winds for January and July over the globe, with an interesting discussion of the leading features exhibited.

Cows, Cow-houses, and Milk. By G. Mayall. Pp. xi+102. (London: Baillière, Tindall and Cox, 1909.) Price 2*s*. 6*d*. net.

The above title covers a lot of ground for a small book of about a hundred pages. Naturally, we expect to find the information much condensed; thus, in the chapter on breeds, little more than a page is given to the premier race, Shorthorns. Again, in feeding cattle and in the variations of milk, we are told, in the one case, a fair ratio is 1 to 6 or 7, and, in another place, ½ lb. to ¾ lb. of good oats is said "to improve fat yield and milk taste." We should have preferred to have seen the starch equivalent and protein in the ration explained in a different way. Breeders, like other people, cannot be expected to agree on all points, and we should wish to have our heifers served long before "at the end of their second year."

The illustrations are very good, and misprints in the reading matter appear to be very few. One may be pointed out on p. 56, concerning the average per cent. of fat in cream, which may be anything from 25 per cent. upwards; also, on p. 63, 40° C. should read 40° F. Of the hygiene and veterinary sections we have nothing but unstinted praise. Everyone interested in this important subject should read "Checking the Spread of Disease." The book can be commended to the improving landowner, the land agent, the dairy farmer, and the short-course student, who requires much information in a limited time.

The Oxford Geographies. (Oxford: Clarendon Press, 1909.) *The Elementary Geography.* By F. D. Herbertson. Vol. II., *In and About our Islands.* Pp. 112. Price 1*s*. Vol. IV., *Asia.* Pp. 128. Price 1*s*. 6*d*. Vol. VII. *The British Isles.* Pp. vi+192. Price 1*s*. 9*d*.

Cambridge County Geographies. Gloucestershire. By Herbert A. Evans. Pp. x+155. *Westmorland.* By Dr. J. E. Marr, F.R.S. Pp. ix+151. (Cambridge: University Press, 1909.) Price 1*s*. 6*d*. each.

The characteristics of the series of elementary books of geography to which the new volumes under notice belong have been described already in these columns (vol. lxxxii., p. 125). In the three new parts of Mrs. Herbertson's "Elementary Geography," it is satisfactory to find the same simplicity of language, correctness of information, and abundance of well-chosen illustrations which served to make the earlier volumes admirably adapted to the requirements of junior classes.

Both Mr. Evans and Dr. Marr have entered into the spirit of the scheme of the Cambridge County Geographies, and their accounts of Gloucestershire and Westmorland respectively maintain the high standard of the series. Geography is given the same wide interpretation, and the books include a description of the architecture, natural history, and geology of the counties dealt with.

The Atomic Weight of the Radium Emanation.

In a paper by Mr. A. J. Berry and myself read before the Royal Society on December 9, on the thermal conductivities of gases at very low pressures, we showed that for the heavier monatomic gases, neon and argon, the experimental conductivity agreed (as well as could be expected from the present state of the measurements) with that calculated from the kinetic theory from the number of impacts of the molecules per sq. cm. per second and the molecular heat of the gas, assuming perfect interchange of energy on impact.

This suggests a possible means of obtaining experimental evidence on the much-debated question of the atomic weight of the radium emanation. If a moderate fraction of a gram of radium were available the infinitesimal quantity of the emanation would not be an insuperable difficulty, for at the sufficient pressure of 0·04 mm. the emanation from this quantity would occupy the sufficient volume of 2·2 c.c. The pressure of the emanation could be deduced from existing data by means of γ-ray measurements; but also, with hardly any elaboration of the apparatus, an accurate determination of the volume of the emanation could be obtained. For it may be remarked, without in any way reflecting upon the numerous and careful experiments that have been done on this volume since its first determination six years ago by Sir William Ramsay and myself, the purification of the emanation by ordinary methods appears at the best to be imperfect; whereas to an operator experienced in the use of the calcium method, worked out in this laboratory, no difficulty is to be anticipated.

On the view discussed in our paper, the thermal conductivities of the heavier monatomic gases should be inversely proportional to the square root of their atomic weights, so that the atomic weight of the radium emanation could be compared with those of the heavier argon gases by a novel method.

Alkali-syenites in Ayrshire.

It is now well known that a group of basic alkalic rocks of approximately late Carboniferous or early Permian age occurs in central Scotland. Dr. Teall first remarked the teschenitic affinities of some of these rocks in his "British Petrography" (1888). During the recent work of the Geological Survey in central Scotland, many occurrences of teschenite, essexite, and theralite have been recognised by Mr. Bailey and Dr. Flett. In several localities the teschenites pass into picrites of the Inchcolm type. Although the general facies of this group is quite basic, and locally ultra-basic, the presence of acid veins in some of the teschenite intrusions has encouraged the hope that a more acidic phase might be discovered in some of the lesser known intrusive masses of central Scotland, hitherto indiscriminately lumped together as "dolerites."

This hope has been realised by the discovery of a large mass of alkali-syenite at Howford Bridge, near Mauchline. This mass, which is intrusive into the Permian lavas of the central Ayrshire basin, is finely dissected by the river Ayr. It is composed mainly of a peculiar medium-grained rock, consisting of thoroughly idiomorphic felspars, principally anorthoclase, with subordinate albite and orthoclase, a little nepheline, numerous small crystals of ægirine, brown and bluish-green soda-amphiboles (barkevicite and arfvedsonite) in mutual intergrowth, and ilmenite altering to leucoxene. The well-shaped crystals of felspars are loosely crowded together, and the angular spaces between them filled with abundant fresh analcite, which encloses the ægirine and soda-amphibole, as though these had been pushed aside by the crystallisation of the felspars in a thoroughly liquid magma. This rock passes downward into a teschenite by the incoming of purple titanaugite and basic soda-lime felspars, but the latter rock is penetrated by irregular veins of the analcite-syenite.

This occurrence is interesting, inasmuch as there is only one other occurrence of alkali-syenites in the British area, namely, the borolanite and associated syenites of Sutherlandshire. These, however, are probably of Cambrian age. The Ayrshire occurrences are being investigated by the writer with the aid of a Royal Society grant, and it is hoped that an account of these alkalic rocks will be published in a short time.

Collected Works of Sir William Herschel.

I beg to direct attention to a pressing need, namely, the publication of the collected works of Sir William Herschel. The investigations of this great man are practically inaccessible to the vast majority of modern astronomers, and the result is that few have any acquaintance with his writings, or know them only second-hand. In my relations with American astronomers I have met no one who has made a close study of Herschel's papers, and in going over them myself have been obliged to obtain them from distant libraries and abstract the contents by laborious processes. I have been equally impressed with the deep insight into the laws of nature which Herschel shows, and the slight extent to which his conclusions and methods are known to modern workers. Surely you will be willing to lend your voice to the praiseworthy task of awakening the British public to a national duty. When writing the life of Herschel for the "Encyclopædia Britannica" thirty years ago, the late Prof. Pritchard directed attention to the necessity of the publication of Herschel's collected works; but meanwhile nothing has been done. Italy has published the collected works of Galileo, Holland the collected works of Huyghens, while France has published the collected works of several of her great mathematicians and astronomers, &c., as those of Lagrange, Laplace, Fourier, Fermat, &c., and now the Swiss, with commendable effort, are trying to publish the vast collected works of Euler.

Herschel's writings are not very voluminous, and probably could be comprised in one large or two moderate sized volumes; and it seems certain that a thousand copies of them could be sold within reasonable time, so that a good publishing house might safely undertake the risk; but in order to give the work a national stamp it would need supervision by an official committee of the Royal Society, or the Royal Astronomical Society, of which Herschel was the first president.

An International Map of the World.

I have read with much interest, in Nature of December 2, the communication by Sir Duncan Johnston. I must, however, confess that two of his propositions tend to damage the very principle of uniformity aimed at by the original idea.

For if, in the preparation of the map of closely populated districts, another scale (in the details) is to be adopted, the general idea conveyed by the map will be misleading.

The same is the case with altitudes. It is necessary to take into consideration the fact that, in all probability, the metre-unit will be adopted throughout the world in the time necessary for the preparation and issuing of the proposed maps. In the meantime, it should be noted on the sheets for foot-countries: 1m. = 3 feet.

E. Báthori.

Nagybecskerek, Hungary, December 6.

With reference to Dr. Báthori's letter on the article which appeared in Nature of December 2, on the 1/1,000,000 scale international map, I agree with him to the extent that I am fully impressed with the importance of uniformity so far as it can be attained without detriment to the value of the map, but I consider that in some cases uniformity can only be obtained at too great a price.

Dr. Báthori demurs to my suggestion that the detail shown should not be absolutely uniform throughout the world. I can best illustrate my view that too hard and fast a uniformity should not be insisted on by stating a concrete case. The committee proposes, and I think rightly, to show on the map lines of telegraph and post offices. In sparsely settled countries, for example Rhodesia, such information would be useful, and could easily be shown on the map. In the populous London district such information would be of no value, even if it could be shown, and I think that the practical utility of the map would be increased in this case by some departure from strict uniformity. Other similar cases might be given.

With regard to the other point mentioned by Dr. Báthori I am afraid I cannot agree with him that the metre will be adopted throughout the world, and I certainly hope that the completion of the international map will not be postponed until the metre is generally used. In the past and the present the foot has been and is used as the unit of measurement in the United States of America, in Great Britain and Ireland and its colonies and dependencies; practically all records are in terms of that unit, and it must be many years before this unit can be changed, if it ever is. If the countries named do not exceed in area and population those which have adopted metrical measurements, they are, at any rate, large enough to merit consideration. I see no reason why the altitudes in this very large and populous area should be shown on the map in terms of a unit not generally used by their people, nor, on the other hand, do I see any cause why the large and populous countries which have adopted the metrical system should have their altitudes expressed in feet.

It seems to me that, provided the unit adopted is legibly marked on the map and subject to some give and take where the two systems meet, countries using the foot should have their altitudes expressed in feet, and those using the metre in metres. I do not think this would cause material difficulty. The practical advantages of this course seem to me to justify some departure from rigid uniformity.

Duncan A. Johnston.

Eastbourne, December 10.

Positions of Birds' Nests in Hedges.

During the autumn and winter of the past three years I have been observing the distribution of birds' nests as regards position in the hedges. In the fields around this village the following facts are noticed. In hedges running north and south (facing east and west), by far the greater number of nests are found to the east of a line through the length of the hedge. In hedges running east and west (facing north and south), very few are on the north side, some in the centre, but most to the south of the line through the length of the hedge. There seems to be a very good reason why this should be the case, but it would not do to state reasons without more evidence. I have not seen this matter noticed in any book or "paper," and it would be interesting to know how the majority of the nests in other parts of the country are placed. The present is a good time for such observations.

St. Faith's, Norfolk, December 2.

Uranium Ore as a Remedy.

With reference to Mr. H. Warth's letter in Nature of November 11 (p. 38), it may be of interest to record a fact which has come under my notice while engaged in the development of a uranious mine in Turkestan. The ore is oxidised and calcareous, and contains uranium, vanadium, and copper, radium being present in accordance with Prof. Rutherford's formula, which gives the quantity of it in relation to the uranium. The uranium is on the average 3·8 per cent., but in some places reaches the ratio of 30 per cent. and more. Until now the work in the mine has proceeded only in the summer time, and in the winter season the workmen have migrated to the neighbouring coal and copper mines. As I know from the literature of the subject that vanadium and uranium are toxic substances, I instruct the workmen to wash their hands well before going to their dinner and after their work. "We do this," they say, "but at the same time we know that in actual practice a cut on a hand, which lasts for a long time in a coal mine, here, when powdered by the ore, gets well very quickly."

Lunar Rainbow of December 1.

ON Wednesday, December 1, about 11 p.m., we saw here a very fine lunar rainbow. It was a perfect bow in the west, showing on a black sky. At the two ends the colours of the rainbow were to be seen quite plainly, though there was only about half a moon. Had there been a full moon, the sight would have been very fine. The rainbow was visible for about twenty minutes.

RICHENDA CHRISTY.

Orchards, Broomfield, Chelmsford.

THE TERCENTENARY OF THE TELESCOPE.

THE year 1609 is one of the most remarkable epochs in the history of astronomy. In the summer of that year Kepler's book on the motion of Mars was published, in which for the first time the actual orbit of a planet in space was determined, while astronomers had hitherto only been able, with more or less success, to investigate the projection of that orbit on the celestial sphere. In the same year the newly-invented telescope was directed to the heavenly bodies, and enabled mankind to form an idea of their constitution, instead of being, as hitherto, reduced to making wild guesses on this subject. But while many years had to pass before Kepler's work became generally recognised (even Galileo never accepted it), the telescope at once became an indispensable tool to astronomers.

Though many attempts have been made to prove that some of the ancient or mediæval philosophers made use of telescopes, it is now generally acknowledged that the telescope was not known to anyone before the year 1608.[1] On October 2 of that year Johan Lipperhey, a spectacle-maker of Middelburg, submitted to the States General an instrument for seeing at a distance, which he had invented, "as was known to the members of the States," and demanded either a patent for thirty years or an annual pension. The States General desired the inventor to produce a binocular telescope, and when he did that they eventually paid him 900 florins for three instruments of this kind, while the patent was refused on the plea that the invention had already become known to many people. These facts are certain enough, but it is quite possible that Lipperhey may not have been the first to construct telescopes, but that the claims of Zacharias Janssen, another spectacle-maker of Middelburg, may be well founded. It appears that this man had invented a compound microscope in 1590. A story was current early in the seventeenth century that some children, when playing with lenses, had found that a weathercock viewed through two of them appeared much enlarged and turned upside down, and that this led to the invention of the telescope. But a telescope which produces an inverted image must have been the so-called astronomical telescope soon afterwards invented by Kepler, which has a convex eye-lens, and not the Dutch or Galilean telescope with a concave eye-lens of which the modern opera-glass may serve as a specimen. A man who had invented a compound microscope would not be unlikely to possess lenses good enough to produce a fair image of a weathercock, and to have been capable of modifying this accidental discovery by substituting a concave eye-lens to make the image upright. Some person is said to have gone to Middelburg to procure a telescope from the spectacle-maker there, but to have applied, by a mistake, to Lipperhey, who thus first heard of the invention.

Whether Lipperhey or Zacharias Janssen was the first to make telescopes will probably never be settled with absolute certainty, but in any case the first telescopes were undoubtedly made in Middelburg. In the introduction to the catalogue of his library (p. xviii), Libri describes a small tract printed at Lyons and dated November 12, 1608, in which mention is made of "nouvelles lunettes" made by a poor, pious and God-fearing man of "Mildebourg"; and the writer states that "even the stars which ordinarily do not appear to our view and our eyes on account of their smallness and the weakness of our vision may be seen by this instrument." From several other contemporary sources we know that knowledge of the new invention spread very rapidly, so that telescopes were not difficult to procure in the spring of 1609, both in the Netherlands and elsewhere. In December, 1608, the States General sent two telescopes made by Lipperhey to King Henry IV. of France; others were publicly offered for sale in Paris about the end of April, 1609, while the news of the invention had reached Venice in December, 1608, and a specimen of the new instrument was brought to Milan in the following May. The wonderful new toy was so very simple that it is not strange that "there was nobody who did not say he had invented it," as a contemporary writer tells us. Among these was Galileo, who in August, 1609, on the Campanile of San Marco at Venice, exhibited a telescope made with lenses purchased in that city. He claimed to have merely heard that a certain Belgian had presented to Prince Maurice of Nassau a glass by means of which distant objects were seen as clearly as if they were quite near, and that this meagre information sufficed to enable him in a single night to design a telescope. If the information received by Galileo was really as scanty as he says, it is very strange that the man who from it constructed a telescope should shortly afterwards, in his "Sidereus Nuncius," show that he hardly had grasped the most rudimentary notions as to the passage of rays of light through lenses and the formation of images. He would have done better if he had followed the explanation of the effect of convex and concave lenses given by Kepler in his book on optics, published in 1604.[1]

But even if we cannot give Galileo the credit which he demanded of having re-invented the telescope, and though, as we have seen, others before him had pointed a telescope to the stars, he deserves full credit for having at once grasped the great possibilities offered by the instrument, and for having made the first serious attempt to explore the heavens with it. He did not grind the lenses himself, but made use of such as he could purchase. Judging by the very rough sketches of the lunar surface given in his little book "Sidereus Nuncius" (published in March, 1610), his small telescopes, magnifying from three to thirty diameters, cannot have been very good; still, they were sufficient to show that the moon was a body like our earth, having mountains and plains, that the Milky Way really was composed of innumerable stars; and, above all, they enabled him to discover the four satellites of Jupiter in January, 1610. Continuing his work, he detected in the following autumn the phases of Venus and Mars, and about the same time he became greatly puzzled by the peculiar appearance of Saturn, which planet, instead of showing a round disc, seemed to be "triple." This continued to be an unsolved riddle for nearly fifty years, until Huygens, by using much improved telescopes, showed that it was caused by a detached flat ring round the planet.

---

[1] See in particular Thomas Henri Martin's paper "Sur des Instruments d'Optique faussement attribués aux Anciens par quelques Savants modernes" in Boncompagni's Bulletino, iv., 1871

[1] "Opera ed. Frisch," ii., p. 56.

In the meantime, other observers lost no time in taking up the new study of the heavens. Before the end of 1608 Simon Marius, of Anspach, procured a telescope with which he found the satellites of Jupiter one day later than Galileo did. He continued for some years to follow their motions with great perseverance and skill, and produced valuable tables of them in his "Mundus Jovialis," published in 1614. Unfortunately, he roused the jealousy of Galileo, who accused him of plagiarism, an accusation which, up to a few years ago, most historians of science were inclined to consider proved, but which has now been thoroughly disproved by a detailed study of the observations of Marius by Oudemans and Bosscha. Marius was also the first to notice the phases of Mercury and the spurious discs of the fixed stars, which the imperfect telescopes of Galileo had failed to show. Even to the sun was the new instrument directed; Galileo says he saw the sun-spots in the summer of 1610, but he does not seem to have taken any interest in them at first, and did not, as usual, announce the discovery, either openly or through an anagram. Thus Johan Fabricius was the first to publish the discovery of sun-spots early in 1611, though Galileo made up for his hesitation by systematic observations, and by being the first to recognise that the spots are formations at the surface of the sun itself, and not bodies moving round the sun, as Scheiner, the third and most assiduous observer of sun-spots, for a long time maintained.

The Dutch or Galilean telescope did not for long remain the only telescope used by astronomers. Already in 1611 Kepler published his "Dioptrice," in which he clearly showed the effect of combining various lenses and the advantages of the "astronomical telescope," in which a real image of the object is formed by the object-glass at the focus of the latter, which is viewed through a magnifying convex eye-lens. A year or two later Scheiner, and following him Fontana, actually constructed and made use of telescopes of this kind, while the inconvenience of the inverted image produced by them was obviated by the introduction of an additional lens in the "terrestrial telescope" to re-invert the image formed by the object-glass. The importance of the real image, which allows a wire or a wire-cross placed at the focus to be seen through the eye-piece as sharply as, and coinciding with, the image, was recognised about 1640 by William Gascoigne, who applied a telescope to a quadrant for measuring altitudes, an application which had been suggested in 1634 by the French astrologer Morin, who, however, only possessed a Galilean telescope. Outside England Gascoigne's idea probably remained unknown, and it was not until 1667 that Auzout and Picard applied telescopes to measuring instruments, and thereby immensely increased the accuracy attainable in astronomical observations.

The importance of the invention of the telescope for the advancement of astronomy is not to be measured only by the insight it gave into the nature of the heavenly bodies, and the aid it rendered in following their movements more accurately. It also rendered an important service by making the Copernican system appear more natural and reasonable in the eyes of every unprejudiced thinker. Hitherto this system had probably to most people appeared to be nothing but a new way of "saving the phenomena" (to use an expression of the ancients), that is, a new method of calculating the motions of the planets, which anyone might use, whether he believed in the reality of the earth's motion or not. Two circumstances had contributed to give an appearance of unreality to the new system; first, the numerous epicycles which Copernicus had been compelled, like the ancients, to use in his planetary theories (because he did not know the first two of Kepler's laws, and therefore had to confine himself to combinations of circles), and secondly, the spurious preface which, without the knowledge of Copernicus, had been added to his book, in which the system was spoken of as a mere hypothesis which need not be supposed to be true. To assume the earth to be one of the planets was also a difficult thing, so long as absolutely nothing was known about the other planets. As to the moon, the ancients had supposed that it must be a body rather like the earth, and the telescope only confirmed this hypothesis. But adversaries of the Copernican system had always asked how the earth could carry the moon along with it during the annual motion round the sun, or why the moon alone should form an exception to the general rule by moving round a planet instead of round the sun? Now Galileo could point to the undeniable fact that Jupiter, during its orbital motion, carried four satellites or moons along with it. The discovery of the phases of Venus and Mercury deprived opponents of Copernicus of another favourite weapon, for they had been wont to proclaim that if Venus moved round the sun it ought to show phases like the moon. Again, the discovery of sun-spots, objects of a temporary nature, supplied a very striking proof that the Aristotelian doctrine of the immutability of all things celestial would have to be given up. While the analogy between the earth and the planets grew stronger every day, it was also of great importance that the fixed stars in the telescope appeared as mere luminous points, so that the apparent diameters of several minutes attributed to them by all previous observers were proved to have no existence. This put an end to the serious objection raised by Tycho Brahe, the greatest practical astronomer since Hipparchus, that a star having no annual parallax and yet showing a considerable apparent diameter must be incredibly large.

As it were in a twinkling of an eye, the whole aspect of the universe had been changed by the invention of the telescope. That this was felt in some way, even by determined enemies of the idea of the earth's motion, may be seen from the statement made by Clavius, the chronologist, in 1611, that astronomers would have to look out for a system which would agree with the new discoveries, as the old one would not serve them any longer. The question could no longer be, "Do you believe in the earth's motion?" it could now only be whether the arguments in favour of this motion were becoming so irresistible that the safest thing to do for its opponents would be to proclaim the doctrine to be heretical. This was accordingly done little more than seven years after the invention of the telescope. J. L. E. Dreyer.

THE YUCHI INDIANS.[1]

Anthropologists have exaggerated the evolutionary gulf between civilised and uncivilised peoples. The more we learn of the latter the narrower does the gulf appear. A remarkable case in point is that of the Yuchis of Oklahoma, recently studied by Mr. F. G. Speck.

Here we have a people engaged in agriculture and cattle-raising, like their white neighbours, wearing the same European dress, and hardly distinguishable from them except in language and colour. It is actually the fact "that many negroes and some poor whites as well are eager enough to work for the

---

[1] University of Pennsylvania. Anthropological Publications of the University Museum. Vol i., No. 1, "Ethnology of the Yuchi Indians." By Frank G. Speck. (Philadelphia: University Museum, 1909.)

Indians on their plantations." Yet this people possesses a perfect set of the primitive ideas and practices illustrated in "The Golden Bough." Totemism, tabu, initiation, exogamy, reincarnation, the couvade, new fire, and the medical practice and food regulations found among the rude Australians—these and other primitive ways flourish here. They are not "survivals," but living realities, forming the warp of the social fabric.

This meeting of old and new may be partially realised by the illustration, here reproduced, of the "new fire" ceremony, which forms part of the New Year festival.

The Yuchis constitute an independent linguistic stock. A hundred years after their incorporation with the Creek Confederacy they left Georgia for the west of the Mississippi, in 1836. They now number about 500, in three "towns," and are "a remarkably strong and healthy set of people."

The clan-system is in use, based on maternal descent and totemism. The members are relatives and descendants of certain pre-existing animals, the *oiaron* of other American tribes. The Bear clan worships and protects the bear, getting bear's meat from the Deer clan, and so on. Above the clan-system is the Society or Class. The entire male population is divided into the Chief Society and the Warrior Society. Above this is the Town or Tribe.

New Fire Rite. Second Day, Annual Ceremony.

Mr. Speck's careful inquiry brings out several interesting points. Students of ballistics will be glad to know that the principle of "rifling" was used in barbarous ages. It is applied to the feathers of arrows. They are twisted so as to make the arrow revolve in its flight.

An important phase of animistic theory is connected with birth. Until the fourth day the child has not "severed all the bonds which link it with the supernatural." On that day it is fed for the first time, and receives a name. "It is then *no longer a half-spirit, but a real human being,* and belongs to earth." (My italics.)

The origin of the tribe is traced to the Sun, and at the New Year festival the town-square is represented as a rainbow. This festival is a good example of primitive ritual, comprising fasting, various tabus, scarification, the rite of the emetic, totemistic drama, inoculation against evil during the coming year, the kindling of sacred fire, and the ceremonial eating of the new corn.

Mr. Speck's interests are chiefly linguistic, but he has made a valuable contribution to general ethnology. The Pennsylvania University Museum is to be congratulated on its first anthropological publication.

MALARIA AND ITS INFLUENCE ON NATIONAL HISTORY.

WIDESPREAD disease, in the form of plagues and pestilences, has profoundly influenced the course of events, local or national, in various countries. The Biblical narrative contains instances of this, and the black death left its mark on European history; in fact, Dr. Gasquet regards the black death as the most important event of the Middle Ages, and a prime factor in the making of modern England. The presence of disease in a locality may in many ways disturb life and enterprise there. Thus the failure of the early attempts to cut the Panama Canal may in part be attributed to the terrible mortality among the labourers, principally from malignant malarial fevers, and the existence of tsetse-fly disease (which attacks horses, &c.) in wide tracts of country in Africa has rendered the problem of transport and the opening up of such districts a difficult one. Prescott, in his "History of the Conquest of Mexico," though writing without the knowledge we now possess, remarks that we find no mention in the records of any uncommon mortality among the conquerors, Cortes and his companions. Had yellow fever and malaria prevailed in the country as they have done in more recent times, in all probability the Spanish conquest of Mexico would never have been accomplished.

Similarly, the introduction of diseases into districts previously free from them may so disturb the balance that the subsequent history of such districts may be entirely altered. A modern instance of this is the introduction of malaria into Mauritius. Until fifty years ago or thereabouts this disease was unknown in these islands; it was then introduced, probably from India, and has since caused serious loss through sickness, in life and by depreciation in the value of property.

It is but a step from a consideration of specific local instances such as these to the suggestion that the introduction of diseases which have the capacity of spreading widely may modify the characteristics and subsequent history of whole nations. This theme in the case of Greece and Rome has been elaborated by Mr. W. H. S. Jones, who sees in the introduction of malaria into these empires at least one of the important factors which helped their decline and fall.

In his "Malaria and Greek History,"[1] Mr. Jones corrects and develops the theory put forward in a previous work (see NATURE, March 19, 1908, vol. lxxvii., p. 457), that man, in the struggle for existence, has to compete, among other enemies, with disease-producing parasites, that even if he is not exterminated by the disease-parasite, this may so weaken him that he falls an easy victim to his healthier neighbours.

---

[1] "Malaria and Greek History." By W. H. S. Jones. To which is added "The History of Greek Therapeutics and the Malaria Theory." By E. T. Withington. Pp. x+175. (Manchester: University Press, 1909.) Price 5*s.* net.

Mr. Jones believes that malaria played a considerable part in bringing about the decline of the ancient Greeks, that this disease fell like a blight upon many fertile districts of Greece, as it almost certainly did upon Attica in the fifth century B.C.

He considers it is at least doubtful if Greece were malarious in early times. For the truth of the theory, it is not, however, necessary to prove (which is impossible) that malaria did not exist in early Greece. For, as Prof. Ronald Ross has pointed out in a recent paper,[1] even if the anopheline mosquitoes, which convey the disease, are present, provided the number of infected persons are few, the spread of infection would be slight or stationary, and the disease might fail for centuries to make headway. If, however, a number of infected immigrants make their appearance, endemic cases will increase, first slowly, then rapidly, until suddenly a widespread epidemic will occur.

In the first chapter of the book the prevalence of malaria in modern Greece and its effect on the inhabitants are discussed. In the two following chapters the evidence contained in the ancient medical and non-medical writers of the existence of malaria in ancient Greece is critically examined. The author believes that on the whole it is safe to conclude that malaria was not prevalent to any extent in early Greece; there are but two doubtful references to the disease before 500 B.C. As regards Attica, there is evidence to show that from the end of the fifth century B.C. malaria began to be prevalent. The disease is referred to in the plays of Aristophanes, and the Decelean and Peloponnesian wars gave opportunity for its spread, partly by the immigration of infected individuals, partly by the neglect of cultivation and drainage of the land, and the increase of the breeding places of the mosquitoes induced thereby.

The history of Greek medicine after 400 B.C. shows a decline in the scientific treatment of disease, and a growing popularity of the dream oracle, charms, and other superstitions, which has never been adequately explained; but it is suggested that the prevalence of malaria, which cannot be treated without quinine, might explain the growth of such superstitious practices. This theme is the subject of an interesting essay by Dr. E. T. Withington.

The condition of the Greeks before the final triumph of Rome seems to have been lamentable—they displayed want of good faith and lack of courage, they had lost ambition and cared for little but pleasure, and brutality, cruelty and vice of all kinds were rife. This period coincides, according to the evidence collected by Mr. Jones, with that during which malaria spread and became prevalent, and he believes that this decadence of the Greek character may in part at least be ascribed to the ravages of this disease. An amount of evidence is accumulated to show that in a malaria-stricken country the inhabitants lose their vigour and moral sense, and become degraded physically and mentally.

Turning now to the case of Rome, Mr. Jones, in an interesting essay,[2] from which we shall quote, similarly seeks to show that malaria exercised a powerful (though to a great extent uncertain) influence upon Roman history and Roman life.

Cicero (first century B.C.) records that on the Palatine hill there was a shrine and altar dedicated to the goddess Fever. This altar, we may remark, is also mentioned by Epictetus (Dissertations), and Pliny says that it had State recognition (both first century A.D.). Although *febris* may be used to denote any febrile condition, it usually means malaria, and the deification of fever is clear proof that it played no small part in the lives of the Romans. As in the case of Greece, the problem arises, has Italy always suffered from the plague of malaria? Many writers have pointed out that some districts (*e.g.* parts of Etruria and Latium), which are now scarcely habitable, were at one time the homes of great and prosperous peoples.

In the very early period, Rome was marshy, but the land around it well drained, cultivated, and the home of prosperous communities, and there is no reason to suppose that malaria was present. By 500 B.C. malaria was in the peninsula, Sybaris being undoubtedly infected, and by the end of the Republic, Sardinia, Sicily, Etruria, Apulia, Latium, the southern coast-line, and Rome itself were all malarious. While not to be regarded as one of the causes of the downfall of the Roman Empire, malaria, Mr. Jones considers, greatly influenced the course of events, and was a serious factor in the lives of the Romans.

Mr. Jones has developed his arguments in a decidedly convincing manner with a wealth of references to classical and modern authorities, and if he has not completely proved his case, the contents of his book and essay are very suggestive, as well as being most interesting reading.

A word in conclusion. Is it not possible that malaria has also played a part in this England of ours? There is a consensus of opinion that parts of Norfolk were once much more populated than is the case at present, as witness the numbers of large and beautiful churches that still exist. Again, within a radius of about three miles round Newchurch, in Romney Marsh, Kent, there are some ten old churches and ruins of two or three others, many more than are now required for the needs of the district, which is sparsely populated, and the same obtains more or less for the whole of the Marsh, where anopheline mosquitoes are still abundantly present, as the writer has found. Both Norfolk and Romney Marsh were formerly very malarious. Has malaria been one of the factors causing the depopulation of these localities?

R. T. Hewlett.

STATE AID FOR AGRICULTURAL EDUCATION.[1]

THE annual report on the distribution of grants for agricultural education and research in 1907–8, lately issued, is a notable volume by reason of the excellent discussion of the whole subject by Prof. Middleton, one of the secretaries of the Board. The total amount expended for education was 12,100*l.*, an increase of 550*l.* over the preceding year; the total number of students attending the various institutions was 1313, an increase of 92. The numbers are far from satisfactory in view of the fact that some 10,000 young men probably take up farming each year, whilst a certain proportion of the agricultural students do not go in for it at all, at any rate in England. Why does not the farmer take greater advantage of the opportunities for educating his sons? It is hardly a question of means, for agricultural education is very cheap and scholarships are liberally given; nor is it that the farmers do not know of the existence of the colleges. The real reason, probably, is that the farmer is not satisfied as to the value of agricultural education. Prof. Middleton has drawn up a table showing for different counties the number of men engaged in agriculture, and the percentage of the "whisky money" spent in agricultural education. It is a remarkable fact that the four counties which spend least, 10*l.* or less per 1000 male agriculturists, are purely agricultural, whilst, on the other hand, those with the smallest agricultural population expend about 150*l.* per 1000 male agriculturists. In spite of all that has been said and written on the subject, Prof. Middleton is driven to conclude that "if we except the organised work connected with the institutions, nothing approaching a system of agricultural instruction exists in England."

[1] Board of Agriculture and Fisheries. Annual Report on the Distribution of Grants for Agricultural Education and Research in the Year 1907–8. [Cd. 4802.] (1909.) Price 10*d.*

No one acquainted with the history of agricultural education in England will be astonished at this conclusion, or at the scepticism of the farmer. The first attempts by the old Science and Art Department to foster agricultural education brought the movement into disrepute. The village schoolmaster was encouraged to read up a small text-book, was examined on his knowledge of the text-book, and was awarded a certificate to the effect that he was competent to teach the "principles of agriculture." So long as he remained in his class-room he was secure, but directly the farmer got hold of him and began asking his advice, he was found out. Nor were later attempts more successful. Things are remembered for long in villages, and the movement has in some counties never recovered from the early errors thus committed, whilst practically everywhere these blunders have constituted a sad legacy which has only been lived down by years of hard work on the part of the institutions. These unpleasant facts are recognised, but are not allowed to paralyse further endeavours, and Prof. Middleton proceeds to sketch out a plan of agricultural education.

In the first instance, the general elementary education in country districts must be such that it arouses the intelligence of the boys and brings them to see the advantage of higher education. A beginning in this direction has already been made. Between the age of fourteen and seventeen the boy should still receive a general education either in secondary schools or at evening schools, according to his circumstances. He will not specialise in agriculture, but will develop what he has already learned, be trained to read intelligently and to observe closely. He may form collections of insects, grasses, minerals, &c., but the subject itself is of less moment than the ability of the teacher to teach it well. The teacher will presumably be allowed great elasticity in framing his time-table. From the age of seventeen to twenty special systematic instruction is to be given at an agricultural college. After he has left and started as a farmer, his education is continued at local classes by itinerant instructors, who could also deal with those who had not been to college.

In principle the scheme is excellent, but its success would depend entirely on the men whose duty it was to carry it through. The British farmer never appreciates the beauty and symmetry of a scheme, but he can appreciate a man. It was largely through ignorance on the part of the officials of this important trait in his character that the earlier efforts failed. Consequently the problem reduces itself to the provision of a sufficient number of suitable instructors. Unfortunately, Prof. Middleton does not tell us how these are to be forthcoming. He knows they do not exist at present, and he also tells us why. If a student is willing to go abroad, his prospects of earning a livelihood are satisfactory, but not if he wishes to remain in England. Thus it happens that the best men studying in our agricultural departments look forward to a career outside England, and move off to India, South Africa, Egypt, or elsewhere at an early opportunity. There is no reserve of good men. A very important reason lies in the way the colleges are managed. Prof. Middleton is probably the first official to discover that the only person on the whole college staff who receives a salary worth aiming at is the principal. No one, unless he possesses other means, can afford to remain in any other post, and when a well-trained man accepts a position on the staff, he stays only until he has picked up the technical part of his subject, and then takes other work elsewhere. Further, as it is not worth the while of a competent assistant to remain on with a view of becoming the head of the department, he accepts the first good place abroad that offers, knowing he will have to go sooner or later. The consequence is that there are not at the colleges any number of promising young men who could be put into responsible posts and trusted to carry out such a scheme as Prof. Middleton recommends.

It is not simply a case of getting a little more money to pay the staff. A farm is always a one-man business, and the farmer cannot understand anything else. The governing body of the agricultural college has the same bias; it recognises the principal, but not the members of the staff, excepting occasionally and collectively.

There are, however, signs of a change. A movement is already on foot, although little or no reference is made to it in the report before us, for affiliating the agricultural colleges to the universities. If, as we hope, the universities rise to their responsibility, they will see to it that the teaching at what is virtually their agricultural department is as good as in any other department, and they will know how to secure this end. Our hope for the future lies not so much in the action of the local committees, or even of the Government boards, helpful though these may be, as in the action of the universities themselves. As soon as they take the problem in hand matters will be righted, and the supply of young men wanted for such a scheme as Prof. Middleton's, and for the posts that are opening up in the British possessions beyond the seas, will soon be forthcoming.

LORD WALSINGHAM'S COLLECTION OF MICRO-LEPIDOPTERA.

It is not much more than two centuries ago since it was possible in England to regard a taste for collecting insects as presumptive evidence of lunacy; and a century ago Kirby and Spence thought it necessary to reply to the current objections to entomology, which represented it as a trifling pursuit, concerned chiefly with nomenclature, and leading to cruelty.

At a much later period complaint was made in some quarters that none of the trustees of the British Museum was interested in natural history; but for many years past this reproach has not existed, several of the trustees being men of high standing as naturalists, and even specialists in certain groups.

Among the foremost of these eminent specialists is Lord Walsingham, who took up the study of the smaller moths (the micro-lepidoptera) of the world about forty years ago, and devoted himself to the formation of what is now incontestably the finest and most valuable collection of these insects in the world, his lordship having supplemented the large collections made by himself in California, Oregon, South Europe, North Africa, &c., by the purchase of all the most important collections of micro-lepidoptera which came into the market, especially that of Prof. Zeller. In 1901 Lord Walsingham's collection was conveyed to the trustees of the British Museum by deed of gift, on the understanding that the collection should remain in Lord Walsingham's possession as long as he wished. Now, however, it has been arranged that the collection, consisting at present of about 260,000 specimens, and adding about 45,000 species to the small number (estimated at 4000 species) at present in the British Museum, is to be transferred to the Natural History Museum, South Kensington, early next year. The scientific value of such a collection, containing a very large number of types, can hardly be overestimated. We are glad to learn that the present inadequate staff of the museum is to be increased sufficiently to allow of special attention being given to the collection of micro-lepidoptera. Lord Walsingham has also liberally presented his special library relating to micro-lepidoptera to the museum.

The British Museum has previously benefited largely by Lord Walsingham's liberality. He has presented upwards of 15,000 specimens, including many collected during his tour in California and Oregon in 1870–1. In connection with this journey the museum published in 1879 a work on North American Tortricidæ, forming the fourth volume of the quarto series of "Illustrations of Typical Specimens of Lepidoptera Heterocera in the Collection of the British Museum." In this work, which was illustrated by seventeen coloured plates, Lord Walsingham described a large number of new species collected by himself. He also published a small volume on the "Pterophoridæ of California and Oregon," in 1880, illustrated by three coloured plates. Numerous papers containing descriptions of new genera and species of various families of micro-lepidoptera by Lord Walsingham have appeared in various periodicals, especially the Transactions of the Linnean and Zoological Societies, and of the Entomological Society of London (of which his lordship was president in 1889–90), the *Entomologist's Monthly Magazine*, &c.

Lord Walsingham has also presented an interesting collection of British macro-lepidoptera (butterflies and the larger moths), accompanied by specimens of caterpillars, mostly prepared by himself, and about fifty of the cases of British birds in their haunts which form such an attractive series in the Bird Gallery.

In conclusion, we must not omit to record that in addition to these numerous benefactions the museum is indebted to Lord Walsingham for the possession of many large and valuable collections which would not have been obtained except through his interest and assistance.

PROF. HILARY BAUERMAN.

THE world of science, and particularly the mining and metallurgical branches, have suffered a severe loss through the death of Prof. H. Bauerman on December 5 from heart failure, after an illness of nearly three months.

Born in 1833, Bauerman entered in 1851, at the age of eighteen, as the first student at "The Government School of Mines and of Science applied to the Arts" (now known as the Royal School of Mines), where he studied under Lyon Playfair, Andrew Ramsay, and Robert Hunt, and particularly under Percy, of whom he was a favourite student, and later a most intimate friend.

During so long and active a life, and starting under such excellent auspices, it is natural that a man of Bauerman's calibre should have passed through a successful and distinguished career, but only those of his more intimate friends who know the work which he actually performed in addition to the immense amount publicly known can appreciate his services to science, and particularly to its technical applications.

His uncompromising attitude on matters where he believed himself to be right, the misunderstandings caused by the slight deafness which existed during his earlier professional life and continuously increased, and the eccentricities which were part of his personality, and added to his charm, to those who knew him, prevented him from receiving such public honours as were his due. His services as one of the first rank were recognised, however, by the many societies and institutions of which he was a member of council and honorary member, and from which he received so many medals and other marks of appreciation. Among other awards, he received gold medals from the Institution of Civil Engineers, the Institution of Mining and Metallurgy, and the Iron and Steel Institute, to the latter of which he contributed a series of most important papers.

After leaving the School of Mines in 1853, he studied for three years at the Freiburg Mining Academy, and in 1855 was appointed assistant geologist to the Geological Survey of Great Britain.

His first work abroad extended from 1858 to 1863, when, as geologist to the North American Boundary Commission, he gained immense experience in accurate surveying and geological work, and laid the foundation for the careful discrimination and accuracy which characterised all his later work.

From 1864 to 1888, his professional and governmental work took him to most parts of the world except Australasia and his enthusiasm enabled him to gain a store of information on matters other than those relating to his actual work, which his prodigious memory and peculiar ability to employ his knowledge at the right moment rendered available to all who applied to him for help, or delighted those who listened to his, often apparently discursive, talk on general subjects. As a professional man and adviser on technical matters, he was pre-eminent in certain circles, but as an author and teacher he was perhaps better known. He was lecturer on metallurgy at the Firth College, Sheffield, in 1883, and succeeded Percy as professor of metallurgy at the Ordnance College, Woolwich, from 1888 to 1906, when he retired from public service, though not from active life.

It would be useless to attempt any enumeration of the public and governmental positions which he filled, but it may be mentioned that he was examiner in both mining and metallurgy for a prolonged period to the Science and Art Department, an examiner to the Civil Service Commission for Inspectors of Mines, and an outside examiner of students for the Royal School of Mines of London, and for the Camborne School of Mines. Both these positions, and many others, he occupied until his death.

His services to science and technology can only be slightly touched upon, but are, to some extent, perpetuated in his works on "Descriptive" and "Systematic Mineralogy" and the "Metallurgy of Iron," in Phillips and Bauerman's "Metallurgy," in the many valuable papers which he read before learned and especially technical societies, in the large number of notes, reviews, &c., which he contributed, often without signature, to the Press, and in the reports of juries at most of the important exhibitions.

Few of the international exhibitions have been carried through without his help, either as advisor or juryman, and he was probably the last living man who had contributed to the literature published by the juries at the close of the great 1851 exhibition. He was a member of committee and juror, commonly chairman or president, of the mining or metallurgical section, or both, at most of the British and foreign international exhibitions, and one of his latest contributions consisted in two important papers, read before the Iron and Steel Institute, on metallurgy and iron and steel at the Franco-British Exhibition, 1908.

Through the death of Prof. Bauerman one of the few members of the old school, of which his earliest teacher and greatest friend—Dr. Percy—was a type, has been lost to us; one of the most kindly and sympathetic friends to the younger members of his profession has passed away, and a most intimate companion, mentor, and friend has been lost to the writer. Only those who knew him can realise how great a loss is being experienced by his friends, and by the many councils and committees on which he served, and on which his wide experience of men and things rendered him so valuable.

Bauerman, like most great men, died in harness. Even on the day before his death he was occupied in dictating a review on a scientific work, and a few hours before he passed away peacefully in his sleep he was talking of his past labours and of the future work of the younger generation.

George T. Holloway.

THE NATURAL HISTORY MUSEUM.

The Trustees of the British Museum have sent the subjoined correspondence to the *Times*, through Dr. F. G. Kenyon, director and principal librarian of the museum.

House of Commons, December 3, 1909.

Dear Sir Archibald,—At the meeting of the standing committee of the Trustees of the British Museum held on Saturday last at South Kensington, the letters which recently appeared in the *Times* relative to the connection of the Bloomsbury and South Kensington Departments of the British Museum and the relation of their respective Directors were very fully considered. It was unanimously felt that nobody could throw a clearer light upon the matter than yourself; that nobody's voice would be so well listened to; and that nobody's opinion would carry so much weight as your own, if you could be persuaded to give the benefit of your views on the question to your co-Trustees.

I understand that you have recently had occasion to inquire into this matter; may I venture, therefore, to invite you, as one of the Trustees of the British Museum, to be kind enough to inform your co-Trustees of the opinions which you hold upon the subject-matter in question?

If I might venture to suggest, the points upon which it appears to me desirable that we should be informed are (1) whether the Board of Trustees, acting through its standing committee, is in your judgment the best authority for the government of such an institution as the Natural History Departments of the British Museum, and (2) whether, under the existing statutes and rules, the scientific management of the Natural History Museum suffers any detriment from its association with the museum at Bloomsbury.

The Trustees are anxious to be reassured that the management of the Natural History Departments of the British Museum can be usefully, adequately, and properly carried on under the present system, and feel that, as you have recently had the subject before you, and have made special inquiries into it, your judgment upon it would carry special weight.

I may say that, at the meeting of the Trustees on Saturday, November 27, I was instructed by my colleagues to deal with this matter, and I have therefore the less hesitation in approaching you directly upon it.

I beg to remain, yours faithfully,
James W. Lowther.

To Sir A. Geikie, F.R.S., Shepherd's Down,
Haslemere.

Shepherd's Down, Haslemere, December 7, 1909.

Dear Mr. Speaker,—In reply to your letter of 3rd inst. I have pleasure in stating, for the information of my co-Trustees of the British Museum, the opinion which I have been led to form on the questions you refer to me. I may say that the agitation on this subject, which has been carried on, fitfully but persistently, in the public Press for many years, supported as it has been by some well-known men of science, created in my mind the impression that there was probably some ground for the complaints that had been brought forward. But not until recently have I had occasion to make a careful investigation of the facts of the case. The result of this inquiry has been to convince me that the agitation has no substantial justification, but has arisen from misapprehension or ignorance, and that if the actual state of the matter had been realised no agitation ought ever to have been started.

The allegation so constantly made that the Director of the Natural History Museum is under much more than the merely nominal control of the Director and Principal Librarian at Bloomsbury is without any real foundation. It has probably been suggested by the fact that, as both establishments are administered by one Board of Trustees, the financial business of the whole institution is entrusted to a single accounting officer. In this obviously convenient and economical arrangement the supervision has been assigned to the Director and Principal Librarian, to whom, by Act of Parliament, every other officer of the British Museum is subordinate. But he has no power whatsoever of interference in the scientific work or management of the Natural History Museum. The duties and responsibilities of the Director of the Natural History Departments at South Kensington, as laid down in the statutes and rules, are precisely the same as those of the Director and Principal Librarian in regard to the various departments at Bloomsbury. Each of these officers is charged with the independent control of the museum and staff over which he presides. Thus the subordination of the one Director to the other is, for all practical purposes, non-existent.

I cannot conceive of a scheme which, under a board of managers, could more fully secure liberty of initiation and action in each of the two establishments. Both Directors are in immediate touch with the Board of Trustees. This board is not a bureau of secretaries and clerks in a Government department, but a body of cultivated gentlemen, full of sympathy with the objects of the great institution committed to them, anxious to promote its interests, and ready at all times to seek the best expert advice in matters which may lie beyond their personal cognisance.

It is, of course, not to be expected that any set of regulations, how carefully soever they may have been framed, will provide for every contingency that can arise from the effects of personal idiosyncrasies. In the conduct of any public institution it must be assumed that the duties assigned to the various officers of the staff will be discharged with courtesy, good feeling, and loyalty to the service. Where, unhappily, these fundamental qualities prove deficient, friction is not unlikely to arise; but any instance of it can be dealt with by the governing authority, and should not imply the necessity for a revision of the statutes, still less for a reorganisation of the institution. After a fairly wide experience, I have no hesitation in asserting that I know of no establishment, either in this or any other country, wherein more favourable conditions have been provided for harmonious and effective cooperation in scientific work than have been devised by the Board of Trustees of the British Museum for the administration of the important departments committed to their care.

I remain, yours very faithfully,
Arch. Geikie.

To the Right Honourable the Speaker of the House of Commons.

NOTES.

We announce with deep regret that Dr. Ludwig Mond, F.R.S., died on Saturday, December 11, at seventy years of age.

We regret to see the announcement that Sir Alfred Jones, K.C.M.G., who rendered valuable services to science by the share he took in the foundation and endowment of the Liverpool School of Tropical Medicine, died on December 13, at sixty-four years of age.

Mr. W. M. Tattersall has been appointed keeper of the Manchester Museum in succession to Dr. W. E. Hoyle.

We learn from the *Revue scientifique* that a monument is to be erected to the memory of Laplace at Beaumont, in Auge (Calvados), where the illustrious mathematician was born in 1746.

By the will of Mr. G. Crocker, who left an estate of 6,000,000*l.*, Columbia University will receive a fund estimated at 300,000*l.* for the investigation of cancer.

The Stockholm correspondent of the *Times* announces that the Nobel prizes for this year have been awarded as follows:—medicine, Prof. T. Kocher, Berne; chemistry, Prof. W. Ostwald, Leipzig; physics, Mr. Marconi and Prof. K. Braun, Strassburg.

The Rome correspondent of the *Times* states that the second general meeting of the International Institute of Agriculture was held there on December 12, and was fully attended by the foreign delegates, of whom more than one hundred were present.

At the annual business meeting of the Scottish Meteorological Society, held on December 8, Prof. A. Crum Brown, F.R.S., was elected president in succession to the late Sir Arthur Mitchell, K.C.B.; Sir A. Buchan-Hepburn, Bart., and Mr. J. Mackay Bernard, vice-presidents; Mr. R. T. Omond and Mr. E. M. Wedderburn, honorary secretaries; and Mr. W. B. Wilson, honorary treasurer.

The selected subject of the essay for the Weber-Parkes prize and medals, to be awarded by the Royal College of Physicians in 1912, is "The Influence of Mixed and Secondary Infections upon Pulmonary Tuberculosis in Man, and the Measures, Preventive and Curative, for dealing with Them." All essays, together with any preparations made in illustration of them, must be transmitted to the registrar of the college during the last week of May, 1912.

On November 24, exactly fifty years after the publication of the "Origin of Species," a number of biological and medical societies of the Netherlands met in one of the large halls of the Amsterdam Zoological Gardens (Natura Artis Magistra) to commemorate this event and the immense and beneficial influence which Darwinism has continued to exercise on human thought since then. Addresses were delivered by Prof. Hugo de Vries on Darwin's visit to the Galapagos Archipelago, and by Prof. A. A. W. Hubrecht on Darwin and the descent of man. The hall was crowded to overflowing, and lavishly decorated with plants, a bust of Darwin occupying the centre in front of the platform. Altogether, the commemoration was impressive and the enthusiasm spontaneous.

At the monthly meeting of the governors of the Imperial College of Science and Technology held on December 10, a letter was presented from Dr. Henry T. Bovey, F.R.S., tendering his resignation as rector. It is understood that this step has been taken owing to the condition of Dr. Bovey's health. The resignation, which came as a great surprise, was accepted with the deepest regret, and reference was made to the rector's great devotion to, and keen interest in, the important work which he had so recently undertaken, and to his unfailing courtesy and consideration in his dealings with all. Dr. Bovey was appointed rector in May of last year; and the new institution has derived a great advantage from his organising power and educational experience. The governors will shortly appoint a successor.

The *Times* of December 9 gives an account of the results of a successful expedition, under MM. Paul Pelliot and Nonette, which has just returned from Central Asia. The mission was equipped by the Comité de l'Asie française, the Ministry of Public Instruction, the Académie des Inscriptions et Belles Lettres, and a number of other societies, aided by private subscribers, the total cost being about 16,000*l.* It has accomplished topographic surveys (by Dr. Vaillant) over a distance of 3000 kilometres, on a route from Andijan, in Russian Turkestan, to Chongchu, on the Peking-Hankau line, across the Taldyk Davan range, where a height of 13,000 feet was attained. The results have been remarkable from the point of view of natural history and anthropology, but the archæological and bibliographical discoveries have surpassed all expectations. At Twen Hwang wooden statues and paintings on silk, alleged to be of date anterior to the eleventh century, were secured, also a whole library, including a Nestorian manuscript, printed records, and records stamped on wood, of the seventh century, most of them unknown in Europe and in China itself. These collections will be added to the Chinese section of the National Library.

A statement of the progress being made with the preparations for Captain Scott's Antarctic Expedition has been communicated to Reuter's Agency. Dr. Wilson, chief of the scientific staff, will also be the zoologist and artist. It is anticipated that three geologists will accompany the expedition, and that one of these will be Mr. Mackintosh Bell, director of the Geological Survey of New Zealand, who has volunteered his services. Mr. R. Simpson, of the Indian Survey Department, will be the physicist of the expedition. He is now on his way to England from Simla. A second physicist will be taken. There will be two, or possibly three, biologists. With Dr. Wilson will be associated a second medical man, who will study botany and bacteriology, giving particular attention to the investigation of blood parasites. The services of Mr. C. R. Meares, who lately completed a journey on the Chino-Tibetan border, have been secured for the expedition. He will leave England almost at once for eastern Siberia to obtain the ponies and dogs. He will collect the animals at Vladivostok, from which place they will be sent to Kobe and trans-shipped for Australia and New Zealand. Mr. Meares will join the expedition in New Zealand.

We learn from a report recently issued by the United States Department of State that during the first Pan-American Scientific Congress, held at Santiago, Chile, in January last, the following resolution on the universal time system, based on the Greenwich meridian, was submitted by Prof. David Todd, of Amherst College, U.S.A., and unanimously adopted:—Whereas (1) in the relations between the peoples of the world, diplomatic, commercial, or other, a standard of time is a common and well-recognised benefit to all; and whereas (2) the world standard of universal time, based on the division of the globe into hourly belts reckoned from a common origin, has now been in use with indisputable advantages since November 18, 1883, in certain countries; and whereas (3) practically all the European countries, Egypt, South Africa, India, Burmah, Australia, Japan, New Zealand, Canada, the United States, and other countries, have already adopted this system of universal time; and whereas (4) the necessary time-signals are now sent out daily, with all essential accuracy and without cost, throughout the American continent, by cable or wireless telegraphy: *Be it resolved,* that the first Pan-American Scientific Congress urge upon such Governments as may not already have taken this step the adoption of the universal time system referred to the meridian of Greenwich, to be effective from January 1, 1910. This comprehensive endorsement of world time by the Latin-American countries forms a fitting recognition of the twenty-fifth anniversary of the inception of a time system which has wrought all the advantages that its originator, Sir Sanford Fleming, foresaw. At the instance of Prof. Todd's representations to these Governments, both Peru and Panama had already adopted standard time officially in 1908.

THE sixty-first meeting of the American Association for the Advancement of Science is to be held in Boston, at the invitation of Harvard University and the Massachusetts Institute of Technology, from Monday, December 27, to January 1, 1910. The president of the meeting will be Dr. David Starr Jordan, of the Leland Stanford Junior University. Addresses of welcome will be delivered by Dean W. C. Sabine for Harvard University and by President R. A. Maclaurin, of the Institute of Technology. The retiring presidents of the sections, with the subjects of their addresses, so far as announced, are as follows:—mathematics and astronomy, Prof. C. J. Keyser, the thesis of modern logistic; social and economic science, Prof. W. G. Sumner; geology and geography, Mr. Willis; zoology, Prof. C. Herrick, the evolution of intelligence and its organs; physics, Prof. K. E. Guthe, some reforms needed in the teaching of physics; botany, Prof. H. M. Richards, the nature of response to chemical stimulation; chemistry, Prof. L. Kahlenberg, the past and future of the study of solutions; physiology and experimental medicine, Prof. W. H. Howell; mechanical science and engineering, Prof. G. F. Swain, the profession of engineering and its relation to the American Association for the Advancement of Science; education, Prof. Dewey, science as a method of thinking and science as information in education; anthropology and psychology, Prof. R. S. Woodworth, racial differences in mental traits. The presidents of sections for the meeting are as follows:—mathematics and astronomy, Prof. E. W. Brown, Yale University; physics, Dr. L. A. Bauer, Carnegie Institution; chemistry, Prof. W. McPherson, Ohio State University; mechanical science and engineering, Mr. J. F. Hayford, U.S. Coast and Geodetic Survey; geology and geography, Mr. R. W. Brock, Canadian Geological Survey; zoology, Prof. W. E. Ritter, University of California; botany, Prof. D. P. Penhallow, McGill University, Montreal; anthropology and psychology, Dr. W. H. Holmes, Bureau of American Ethnology; social and economic science, Mr. B. W. Holt; physiology and experimental medicine, Prof. C. S. Minot, Harvard Medical School; education, Prof. J. E. Russell, Columbia University, New York. A popular lecture will be given during the evening of December 28 by Dr. C. W. Stiles, of the Boston Public Health and Marine Hospital Service, on the hook-worm disease in the south.

WE have to acknowledge the receipt of a copy of an article on Darwin, by Prof. A. A. W. Hubrecht, published in *De Gids*, No. 12; also of one by Dr. Angel Gallardo on "Las Investigaciones Modernas sobre la Herencia en Biologia," extracted from a volume published at Cordoba to commemorate the retirement of Dr. R. Wernicke from the faculty of medicine. The latter deals largely with the main principles of the Mendelian theory.

CRUSTACEANS form the subject of two articles published in part i. (London: Williams and Norgate) of a report to the Government of Baroda on the marine zoology of Okhamandal, in Kattiawar. In the first of these Messrs. J. Hornell and T. Southwell describe a new species of pea-crab of the genus Pinnoteres infesting window-oysters (Placuna), and remarkable for the number and large size of the males, while in the second Mr. Southwell discusses the anomurous crustaceans of the same area.

THE practical improvement of ethnological collections in provincial museums forms the subject of the chief article in the November number of the *Museums Journal*, the article being an address read by Mr. F. W. Knocker at the Museums' Conference at Maidstone last summer. It is pointed out that valuable objects of this nature preserved in local museums are frequently assigned to countries wholly different from those from which they originally came, and that urgent need exists for intelligent geographical classification of such collections.

To the Transactions of the Edinburgh Field Naturalists' and Microscopical Society for 1908–9 (vol. vi., part ii.) the Rev. D. W. Wilson contributes some interesting notes on birds mentioned in early Scottish literature and documents, from which it is made evident that the crane was formerly common in Scotland, thus adding strength to the opinion of the late Mr. T. Southwell that it formerly bred in East Anglia. In another paper in the same issue Mr. J. C. Adam directs attention to the long nesting-period of the more typical members of the crow-tribe, a fact to which no allusion appears to be made in bird-books. Fourteen days for incubation and another fourteen for the nestlings to acquire their feathers is, for instance, the length of the nesting-period in the case of the thrush. In the case of the rook, on the other hand, the eggs are brooded for seventeen days, and the young require another twenty-seven or thirty days in the nest, making the whole nesting-period nearly seven weeks. The carrion-crow requires an additional week, while the raven seems to take about a week more than that species.

THE need of a regular study of the sequence of plumages in birds forms the subject of an editorial article in the December number of Witherby's *British Birds*. It is pointed out that when a bird first leaves the nest it is either naked or clothed with a down-plumage. The latter is succeeded by a juvenile plumage, acquired by a complete moult. In a few instances this juvenile dress may perhaps be indistinguishable from that of the adult, but in most cases, at any rate, it is generally possible, and often easy, to differentiate between the two. In some instances, when the dress of the adults of the two sexes is different, the juvenile plumage approximates more or less closely to that of the female, but more commonly it is markedly different from that of both adults. It may be spotted or streaked, it may show light borders to the feathers, it may be duller than that of the adult, or may be altogether distinct. It is proposed to institute a careful study of these early plumages of British species, and then of their successive summer and winter liveries season by season.

IN a report on the progress of game-protection in the United States during 1908, published in the Year-book of the Department of Agriculture, Mr. T. S. Palmer states that the year 1908 was not marked by any event of special importance, but a number of factors, at least in certain localities, affected the condition of game and the success of the hunting season. On the whole, the game wintered well, and conditions in the spring were better than normal. During the summer a prolonged drought, accompanied by forest-fires, occurred in several of the northern States, and threatened serious injury to deer and grouse, but the loss proved less than predicted. In the Carolinas and Georgia floods in August and September caused great destruction of deer and wild turkeys. The difficulty of obtaining game-birds for stocking coverts increased interest in the grey partridge of Europe, and resulted in the importation of a much larger number of these birds than in any previous year. The rapidly increasing popularity of the automobile and the motor-boat in the pursuit of game is apparently affecting the abundance of certain species in some localities, and indicates the necessity for better regulation of such methods of hunting.

In a recent number of the Proceedings of the Zoological Society of London (October) Dr. F. Wood-Jones gives an abstract of his remarks on the new theory he has formulated on the origin of coral reefs and atolls. According to his view, the presence or absence of sedimentation determines, in the first place, whether the reef corals are not, or are, able to form a reef on a submerged bank. The tendency of reefs, once started, to become "basin-shaped" is due to the sediment that falls and settles on the side of the reef that is protected by the growing corals from the washing action of the sea currents. When the reef reaches the tide limit the waves hammer fragment against fragment and form a quantity of coral débris, which becomes cemented into a solid breccia to form the basis of the coral island. A small coral island once formed in this manner provides an impediment to the current, and the burden of sediment the current carries is deposited in stream lines from its extremities. "In this way the form of the island tends to becomes a crescent." The theory is ingenious and full of interest, but until the full paper, which we may hope will be adequately illustrated, is before us, it is difficult to believe that it will entirely supplant the older theories of "subsidence" or of "solution." Neither the simple and beautiful theory of Darwin nor the more complicated but still fascinating theory of Sir John Murray have received universal support; it is hardly possible that Dr. Wood-Jones's theory of sedimentation will prove to be capable of solving all the difficulties.

The first appendix to the *Kew Bulletin*, 1910, has been issued. It contains, as usual, the list of seeds of hardy herbaceous plants and of trees and shrubs which have ripened at Kew during the year and are available for exchange with botanic gardens and regular correspondents.

A paper of much interest contributed by Dr. Th. Weevers to *Recueil des Travaux botaniques Neerlandais* (vol. vi.) discusses the physiological significance of some glucosides. The author previously studied the glucoside, salicin, present in twigs of *Salix purpurea* as a reserve product, and observed that when the shoots start growing it gives place to a body saligenin, and apparently this in turn to catechol. He now reports the discovery of the enzyme, salicase, which decomposes salicin. Further, he identifies two oxidation ferments, which act upon saligenin and catechol respectively. These and other results lead to the following argument. During the summer salicin is formed in the leaves by day, but is decomposed by night, and the glucose is transported to the cortex; each day the catechol combines with more glucose to form salicin. In the autumn the process ceases, because the cortex contains as much salicin as the leaves. These conclusions agree with the hypothesis that benzene derivatives combine with carbohydrates to form substances which diffuse with difficulty, and that serve to keep the sugar stored in the tissues.

An essential feature of the scientific investigations undertaken at the Rothamsted Experimental Station is the practical bearing of the problems involved; this is evident in the papers originally published in the *Journal of Agricultural Science* (October), now issued in pamphlet form from the Cambridge University Press. A communication by Drs. E. J. Russell and H. B. Hutchinson deals with the effects produced by partial sterilisation of soils. When a soil is heated to 95° C. or treated with volatile antiseptics, *e.g.* carbon bisulphide, it becomes more productive for a while. The authors find that there is an increase in the production of ammonia, which is due to a rapid increase of bacteria. Reasons are given for believing that the chief factor is the destruction by sterilisation of large competing organisms of the nature of protozoa. If this be so, it is possible that some method may be devised for suppressing these undesirable soil organisms, and the authors state that this practical question is receiving attention. Drs. H. B. Hutchinson and N. H. J. Miller have attacked the problem of nitrogen assimilation by plants to test the evidence in favour of direct absorption of ammonium salts. Experiments were conducted with wheat and peas grown in water and sand cultures under the conditions necessary for excluding nitrifying organisms. The results show that these plants can take up their nitrogen entirely in the form of ammonium sulphate, although wheat thrives better when supplied with a nitrate. It is mentioned that other investigators have found a partiality for ammonium salts in the early stages of a plant's existence, while nitrates have been necessary or more fruitful in later stages.

Solid carbon dioxide is now being used for refrigeration in the treatment of certain affections of the skin. The substance is obtained in the form of a snow by allowing the gas to escape from a cylinder in which it is compressed. This snow is placed within a tube of metal or vulcanite, and packed by using a solid rod which fits into the tube as a rammer. In this way round or square rods of solid carbon dioxide can be obtained. A rod may be held in the hand with a turn or two of lint intervening, and the free end may be pared to any shape by means of a knife, as it is quite firm. On applying the end of a rod of this kind to the skin with pressure, the frozen surface immediately becomes white and hard. The process of thawing occupies about the same time as the application. Reaction sets in at once, the treated area becoming perceptibly swollen in two or three minutes. A wheal forms within half an hour, and often a blister is produced within an hour, though with short applications this does not occur. An application of thirty seconds or more is followed by scarring. The application is practically painless. The method is chiefly of use in the treatment of capillary nævi of less than 1 inch diameter. The average duration of the application is about forty seconds. "Port-wine mark" is dealt with in this way. Some moles are amenable to this treatment, and it answers well for warts. In the case of warts a longer application is necessary, say one to one and a half minutes, pressure being continued until a narrow zone of healthy tissue is frozen around the base of the wart. Keratoses (horny growths of the skin) are among the diseases amenable to this method of treatment. It is too early to say what will eventually be the scope and limits of the therapeutic utility of this agent, but the method is of interest as an instance of another application of physics to medicine.

It is well known that in animals such as the vertebrates, which have a closed vascular system, the nutrient function of the blood is exercised upon the tissues through the intermediation of lymph, that is, the fluid part of the blood which leaks through the thin walls of the blood-capillaries. The problem of lymph formation is fraught with interest, and has exercised the attention of many physiologists. The word leakage just employed, however, implies that the main factor in its formation is the mechanical one of filtration, but this is by no means the truth, or at any rate the whole truth. Osmosis is another physical process concerned, and the labours of physical chemists in elucidating the laws of osmosis have been important from the physiological point of view; but, in addition to physical forces, the physiological or "vital" properties of the living capillary wall have to be taken into account, and the secretory nature of lymph formation was ably insisted upon by the late Prof. Heidenhain. A somewhat similar set of factors has to be reckoned with in the question of urine formation in the kidneys, and different physiologists hold diverse views concerning the relative importance of the physical and physiological factors concerned. Those interested in the latest development of such discussions, mainly in relation to the formation of lymph, will find them ably discussed in a little pamphlet written by Prof. Asher, of Berne, who has devoted much of his research work in this direction. It is entitled "Der physiologische Stoffaustausch zwischen Blut und Geweben," and though published separately it forms part of a larger work which is being written by collaboration under the editorship of Profs. Gaupp and Nagel, called "Sammlung anatomischer und physiologischer Vorträge und Aufsätze" (Jena: G. Fischer).

MISS E. B. VAN DEMAN contributes to the Proceedings of the Carnegie Institution of Washington an elaborate monograph on the Atrium Vestæ at Rome. This building was first discovered in 1883 at the foot of the Palatine Hill in the Forum, and the excavations have been since carried on at intervals. The investigation of the site is particularly difficult, because, owing to successive outbreaks of fire, the building was reconstructed or restored no less than five times from the Republican period down to that of the later Empire. The most interesting point disclosed by the excavations is that the dwelling of the Vestal Virgins, who guarded the sacred fire, was an adjunct to that of the early king and queen. The queen, as materfamilias of the State, supervised the duties of the Vestals. This fact furnishes strong evidence in support of the theory enunciated by Prof. J. G. Frazer, some five-and-twenty years ago, that the Vestals were originally the daughters of the king, and as such were naturally placed in charge of the sacred fire which was kept alight in the house of the king, and on its maintenance the safety of the State was supposed to depend.

THE December number of the *Geographical Journal* contains a second interim report of the committee of the society on progress in the investigation of rivers, by Dr. Aubrey Strahan. The chief work of the year includes observations of flow, temperature and composition of water, and estimations of dissolved and suspended matter, in the rivers Exe and tributaries, the Medway, and the Severn. A number of notes on special points is appended to the report, and Dr. Mill contributes an extremely valuable paper on the rainfall of the Exe Valley.

MR. V. STEFÁNSSON contributes a short paper on northern Alaska in winter to the Bulletin of the American Geographical Society. The author points out that whereas driftwood was formerly abundant along the entire north coast of Alaska, very little now comes ashore anywhere west or south from Point Barrow, showing that this section of the coast depends for its driftwood on the Yukon River, the banks of which have recently been deprived of much of their tree-growth. A few years ago the Eskimos of northern Alaska might have been broadly classified as inlanders and coast people, but now most of the inlanders have moved to the coast, starved out by the disappearance of the caribou, which has been slaughtered indiscriminately for about twenty years.

IN the Journal of the Scottish Meteorological Society for the year 1908 (vol. xv., third series) Mr. A. Watt, secretary to the society, gives a very interesting summary of the development of the exploration of the upper air by means chiefly of kites and unmanned balloons, from the early experiments of Wilson, Archibald, and others in Great Britain, and Espy, Rotch, and others in the United States, until the present time, together with a brief description of the results relating (1) to the general circulation of the atmosphere, and (2) to the temperature conditions at great heights. It is not claimed that anything new is contained in the paper, but it gives historical notes, and references to original discussions that have appeared in our own columns and other journals of a scientific character, which will be very useful to anyone interested in this important subject. The author thinks that these researches are "perhaps the most brilliant chapter in the history of meteorology."

IN the *Physikalische Zeitschrift* for November 22 Dr. T. Wulf directs attention to the advantages of using calcium carbide as a drying material in electrostatic instruments the insulation of which is to be maintained. He has found that a small piece of the substance will keep the interior of an electroscope he uses for measuring the γ rays from radio-active materials quite dry for several weeks, although the instrument stands in the open exposed to rain. The active surface of the material is kept free owing to the dry powder due to its action falling from the surface as it is formed. The efficiency of the carbide seems to be rather better than that of sodium.

MISS LAURA L. BRANT, of the Brown University, Providence, gives in the November number of the *Physical Review* the results of her re-measurement of the magnetic and electrical properties of a score of steel rods which were made glass-hard and then tested by Prof. Barus in 1885. They were again tested by him in 1888 and in 1897, so that we now have a record of the change of the properties of this steel when kept at ordinary temperatures for twenty-four years. In all cases there has been a diminution of the electrical resistivity of the steel of about 20 per cent. in the twenty-four years, the change having taken place along an exponential curve. The same result would have been reached in three hours if the rods had been heated to 100° C. Miss Brant concludes that glass-hard steel will, if kept at ordinary temperatures, be completely softened in 250 years.

MR. E. MERCK, 16 Jewry Street, E.C., has issued his annual report of recent advances in pharmaceutical chemistry and therapeutics for 1908, vol. xxii., dated from Darmstadt, August, 1909. The present volume has grown to nearly 400 pages, the index of authors alone covering thirty columns, and including more than 1000 names. A hundred pages are devoted to a monograph on organotherapy and organotherapeutic preparations, the remainder of the report being occupied with detailed notes on preparations and drugs, these being arranged in alphabetical order for convenience of reference.

MR. L. OERTLING has sent us a copy of his new illustrated catalogue of assay, chemical, and bullion balances. More than fifty balances are illustrated, ranging from a bullion balance constructed to carry 10,000 oz. and turn with 10 grains, to an assay balance carrying 1 gram and weighing to 0·005 milligram. Among the new balances not previously shown is the ampere balance made for the National Physical Laboratory, weighing to a milligram when loaded with 5 kilograms in each pan. In the case of the weights, it would be desirable to indicate the accuracy of adjustment, if only as explaining the apparent anomaly, a set of weights ranging from 50 grams to 1 milligram being quoted at 2*l.* 5*s.* on p. 59 and at 15*s.* on p. 61.

Messrs. Gallenkamp and Co., Ltd., have favoured us with a copy of their catalogue of spectroscopes, spectrometers, vacuum tubes, induction coils, and other accessories essential to modern spectroscopical research. After examining the publication carefully we recommend all who are engaged or interested in such work to acquire a copy, for it is plentifully illustrated, the instruments are described in detail, and instructions are given as to how they should be set up for the best use in various researches. The accessories for the production of spectra, such as tubes, burners, coils, and cells, are very numerous, and the firm makes a speciality of vacuum tubes to which we have previously directed attention (vol. lxxi., p. 448). The "C" type of tube, in which the illuminated gas is viewed end on in a capillary tube, without the interference of the electrodes, is now made in Uviol glass and with ground-in quartz windows, so that investigations of the ultra-violet part of the spectrum may be carried out with the various ultra-violet spectrographs figured and described in the catalogue.

Some results of trials of the new transmission gear for marine turbines constructed for Mr. George Westinghouse to the designs of Rear-Admiral George W. Melville and Mr. John H. Macalpine appear in *Engineering* for December 3. In this gear the reduction of speed from 5 to 1 is attained by the use of double helical spur wheels and pinions mounted in such a manner as to secure an even distribution of the bearing pressure between the teeth. The full load to be transmitted is 6000 horse-power at 1500 revolutions of the pinion shaft, and a special hydraulic brake was employed in the tests to take up the load. A few of the results are given in the following table:—

B.H.P. delivered by gear	3712	4156	4576	5036	5486	5927
B.H.P. of turbine	3771	4197	4623	51 8	5567	6057
Efficiency, per cent.	98·7	99	98·9	98·7	98·5	98·7

This efficiency is very remarkable, being as good as has been recorded with the best cut gears of ordinary dimensions. An endurance test of the gear at full load has also been carried out, extending from 3.15 on Saturday afternoon until 7.15 the next Monday morning. During the last thirty-four hours of the run the temperature of the gear remained constant, and there was every indication that the trial could have been extended indefinitely. The performances of this gear on board ship will be looked for with interest, both as regards the working of the gear and the anticipated economy which will result by running both turbine and propeller at their best speeds.

The conditions of award of the prize of 1000*l.* offered by Mr. Alexander for a British-built aëronautical engine have now been issued. We extract the essential conditions from *Engineering*, as follows. The engine must develop not less than 35 brake-horse-power, and not exceed 245 lb. weight; that is, 7 lb. per horse-power, including all parts necessary for running, cooling apparatus, and accessories. Arms suitable for bolting down to a testing bed are included in the weight, and such arms must be arranged so that the motor-shaft is not less than 16·13 inches above the test-bed. The points on which the award will be given are:—(*a*) weight and petrol consumption; (*b*) trustworthiness and steadiness of running; (*c*) wear of working parts; (*d*) security against fire; (*e*) air-resistance offered by motor. Each motor will be tested on a 24-hours' run, and if the stoppages during this time exceed three, or if the total time of stoppage exceeds thirty minutes, the motor will be disqualified. The balancing will be taken into consideration, and the engine will also be tested at an inclination of 15 degrees, first one way and then the other, an hour's run each way being given. A thrust of 175 lb. will be applied during the tests to represent the thrust of the propeller. The tests will be made in an air current of thirty miles per hour. The regulations comprise subsidiary details, but the above are the essentials. The tests will be carried out at the National Physical Laboratory under the sole control of the advisory committee, and entries may be made not earlier than February 1 and not later than April 30 on entry forms which may be obtained from the secretary, advisory committee for aëronautics, Bushy House, Teddington.

Messrs. Longmans, Green and Co. have published a seventh edition of Prof. W. D. Halliburton's "Essentials of Chemical Physiology for the Use of Students." Scarcely a page of the book has escaped revision, and a new lesson on some typical organic compounds has been included in the book.

A third edition of the "Elementary Treatise on Electricity and Magnetism," by Prof. G. Carey Foster, F.R.S., and Prof. A. W. Porter, has been published by Messrs. Longmans, Green and Co. The whole book has been revised, and many additions have been made. The final chapter has been re-written, and provides a good summary of recent progress in electrical science.

Mr. M. Kanade, Baroda, India, has sent us a copy of a list of books he has compiled and classified according to the system, known as the decimal classification and relative index, devised by Mr. M. Dewey, director of the New York State Library. The catalogue does not make it quite clear how the books chosen for classification have been selected, but the scheme provided for the classification of the works in any library should prove useful.

OUR ASTRONOMICAL COLUMN.

Daniel's Comet, 1909*e*.—A second observation by Prof. Daniel of the comet discovered by him on December 6 is reported by a telegram from the Kiel Centralstelle, and the following elements and ephemeris, computed by Dr. Ebell from observations made at Princeton (December 7), Northampton (December 8), and Nice (December 9), are published in Circular No. 116 from the Kiel Centralstelle:—

Elements.

T = 1909, December 5·6011 (Berlin).

$$\left.\begin{array}{l}\omega = 8^\circ\ 16{\cdot}42' \\ \Omega = 73^\circ\ 33{\cdot}08' \\ i = 26\ \ 56{\cdot}90'\end{array}\right\}1909{\cdot}0$$

$\log q = 0{\cdot}19674$

Ephemeris 12h. (M.T. Berlin).

1909	α h. m.	δ ° ′	log Δ	Brightness
Dec. 13	6 18·1	+39 31·0	9·789	0·99
15	6 18·4	+41 6·2		
17	6 18·7	+42 38·8	9·794	0·96
19	6 18·9	+44 8·4		
21	6 19·0	+45 34·7	9·802	0·92

As the comet is travelling northwards through Auriga, nearly parallel to the line joining θ and β Aurigæ, it will probably remain observable in the northern hemisphere for some time.

The above elements show a likeness to those of comet 1867 I., but are, as yet, too uncertain to permit of any definite conclusions.

It will be seen from the ephemeris that the comet is now receding from the sun, and is becoming fainter; the unit brightness, at time of discovery, was given as 11·0.

Halley's Comet, 1909*c*.—A further ephemeris for Halley's comet, based on the assumption that perihelion passage will take place at 1910 April 19·67, is published in No. 416 of the *Observatory* (December, p. 476), and extends to April 5·1 (Berlin Time). In the interval the comet will pass from Taurus, through Aries, graze the northern limit of Cetus, and traverse Pisces. The short time that the orbit plane of the comet lies above the plane of the ecliptic is shown by the fact that the ascending and descending nodes are passed on January 17·9 and May 18·6, 1910, respectively; on the latter date the comet transits the sun. For seventy-eight days it remains inside the earth's orbit, being at unit distance from the sun on March 11·6 and May 28·7 respectively. At the beginning of March the comet will set about three hours after the sun, and will probably be unobservable from the end of the first week until nearly the end of April; then it will become observable before sunrise.

Numerous visual observations are now being recorded. Among others, Prof. Schorr reports that Dr. Graff saw the comet, with the $9\frac{1}{2}$-inch equatorial of the Hamburg Observatory, on November 18, as an elongated nebulous mass, whilst Herr H. Thiele saw it with a $4\frac{1}{2}$-inch comet-seeker. A number of observations are also reported in No. 4373 of the *Astronomische Nachrichten*. According to a *Daily Mail* correspondent, the Greenwich photographs show curious fluctuations of brightness. On November 22 the comet was of the tenth magnitude, whilst on November 30 it was of the twelfth, although on December 1 it was again brighter.

Mars.—In the December number of the *Observatory* the Rev. T. E. R. Phillips briefly reviews the various observations which have been made of the Martian features during the present opposition. His own observations indicate that the polar cap was not symmetrical about the pole of rotation, but was further from the south limb when the central meridian lay between longitudes 300° and 50° than when the other side was presented. The canals, generally, have not been well seen by Mr. Phillips, and only the Euphrates has been seen duplicated. He also refers to the lack of brightness in the white regions so well seen in 1903. Six drawings of the planet, by Mr. Phillips, accompany the note, and illustrate the various points to which the author refers.

Observations of Jupiter.—In No. 4372 of the *Astronomische Nachrichten* Herren H. E. Lau and C. Luplau-Jannsen describe their observations of Jupiter made during the period January–May of this year. Numerous spots were seen in the different bands, the activity of the southern hemisphere in this respect during the recent oppositions apparently exceeding that of the northern. Band iv. appeared redder than hitherto, and the bright central line more irregular. In April a remarkable projection was seen on the southern edge of band v., darker than the band itself, but apparently partaking of the general motion of that region. Important changes took place in the visibility and form of the Great Red Spot between the end of January and the end of March, and on March 28 the spot itself could not be seen, although its place was partially occupied by a bright egg-shaped mass. A discussion of these changes and a number of measures of the various features also form part of the paper.

In No. 4373 of the same journal Dr. H. H. Kritzinger asks that all those observers who have unpublished measures of the position of the Red Spot will kindly communicate the same to him at 7, Hindersinstrasse, Berlin N.W.

A Solar Physics Observatory for Australia.—The importance to solar physics of the installation of a properly equipped observatory in Australia can scarcely be overestimated, and it is therefore with great pleasure that we learn, from the *Observatory*, that the labours of Dr. Duffield and others in this direction are likely ultimately to become fruitful.

At a meeting held on October 26 a number of prominent Australian officials discussed the matter, and His Excellency the Governor-General, Lord Dudley, in a carefully reasoned speech, pointed out the urgent necessity for the establishment of such an institution. He pointed out that a capital expenditure of at least 10,000*l.*, and an annual expenditure of about 1500*l.*, would be necessary, but if Australia is to use the exceptional advantages of position and climate which it possesses, and to take her place among the other nations in the progress of science, this opportunity should not be neglected. After discussing the matter at length, the meeting agreed to the following motion:—"That the establishment of a solar observatory is desirable, and that the Federal Government be strongly urged to assume the responsibility of carrying it into effect." Already some 1000*l.* has been raised among private donors, and it has been officially suggested that the Commonwealth Government will materially help the fund, and, in the event of the effort being successful, provide for the maintenance of the observatory. From the opinions expressed by several influential Australian papers it appears very probable that this much needed institution will ere long become established.

The Hamburg Observatory.—We have received from the director, Prof. Schorr, the reports of the Hamburg Observatory for the years 1907 and 1908. In the latter is an account of the removal of the observatory to Bergesdorf and of the new instruments installed therein.

Ephemerides for Perrine's and Winnecke's Comets, 1909*b* and 1909*d*.—Ephemerides for comets 1909*b* and 1909*d* are published in No. 4374 of the *Astronomische Nachrichten* by Dr. Ebell and Prof. Hillebrand respectively. As both these objects are faint, and south of the equator, it is not worth while reproducing the ephemerides here.

A CONTRIBUTION TO APPLIED BOTANY.[1]

OWING, it seems, to the dilatoriness of some of the contributors, the annual report of the German Society of Applied Botany for 1908 has only lately appeared. The society, now numbering 260 members, held its sixth meeting at Strassburg early in August, and ought not to require twelve months for the publication of its report. A curious feature in it is the separation of the account of the discussion of the contents of a paper from the report of the paper itself. It would be more convenient if the two were combined, and the paper followed by the speakers' observations in each case. Thus "Diskussion zur Appel," early in the volume, refers to a paper by Appel at the end.

Wittmack directs attention to the confusion caused by the want of uniformity in the views expressed by experts on botanical matters, affecting especially the German Customs' Department. He recommended the appointment of a technical committee and the publication of its decisions in a special bulletin. This was subsequently found impracticable, and the society decided to utilise its annual report for such purposes as far as possible. As Wittmack's article itself indicates, the expert forces of Germany are so systematised in the various industries that there is little need for a new organisation.

In this report the amusing case of the "everlasting plant," *Selaginella lepidophylla*, is described in detail. Wittmack reported that the plant, as imported for sale as a curio, is dead. Brick, of the Hamburg Plant-protection Station, however, reported that the imported plants are often, as several botanists have shown, living. Any such living plant imported into Germany must pay a tax and be examined for freedom from vine-louse and the St. José scale-insect. Fortunately, common sense prevailed, and the plants are now allowed into Germany as curios.

Mez compares *Merulius lacrymans* with other forms of dry-rot, and shows that it, unlike, *e.g.*, *Polyporus vaporarius*, prepares its way by moistening the timber with the "tears" it produces by its respiration, from the carbohydrates derived from the timber destroyed by it. The practical importance of this is great.

Klebahn describes experiments on the solvent action of root-secretions on "agriculture" and other phosphates. Wittmack defines the term "bulbs" as used horticulturally.

Voigt shows how seriously the contract cereal trade through Hamburg is affected by a correct application of the term "wild oats" in grain analysis, Hamburg and Berlin differing in their interpretation of it.

Muth contributes a comprehensive account of the varied part botany should play in the experimental work of agricultural stations, and shows that neither botany nor botanists occupy their rightful position at present in

---

[1] Jahresbericht der Vereinigung für angewandte Botanik. Sechster Jahrgang, 1908. Pp. xlii+294. (Berlin: Gebrüder Borntraeger, 1909.)

Germany, especially in comparison with applied chemistry and its followers.

H. Fischer, the discoverer of the symbiosis of N-bacteria with microscopic soil algæ, in a valuable article on soil bacteriology, summarising and discussing the results already obtained, urges the necessity of treating the subject as a botanical one and of encouraging botanists to devote themselves to it if advances commensurate with its practical importance are to be made. Thus at present there is, he states, no known method of bacteriological soil investigation which satisfies the requirements of science and practice. Exclusive of the discovery of the N-fixing power of the bacteria of leguminose roots, little of practical value has so far been ascertained. *Azotobacter chroococcum* is, in passing, quoted as a calcicole plant, thus serving, like some flowering plants, as a soil indicator.

Wieler writes on the smoke nuisance as it affects plant life. He shows how little the subject is understood, urges the creation of a smoke institute for the investigation of smoke problems, and the employment in legal cases of smoke experts as judicial arbitrators. Wieler reviews critically the publications of recent years on smoke, and deals especially with the sulphur compounds on which he has himself worked. The prevention of damage to plant life by smoke is a botanical subject.

P. Sonntag describes the results of his examinations of the ductility and breaking point of the bast fibres of some half-dozen different palms, corrects earlier observations on the subject, and shows the practical bearing of the question, *e.g.*, on the selection of fibres for street sweepers.

Count Arnim, well known for his devotion to the production of new varieties of cereals, contributes a stimulating article on the production of new varieties of potatoes. He contends that hitherto the method pursued has been empirical, the object having been to meet the speculative trade demand for new varieties each year. Scientific men are invited to answer certain questions pressing for solution, and to aid the conscientious practical man in the search for trustworthy starch-producing disease-resisting varieties. Results hitherto obtained in potato-culture experiments are of necessity contradictory, not being based on scientific principles.

L. Bernegau deals with the utilisation of dried potato tubers and of the sweet-potato (batatas) in the German colonies of West Africa. The article is of value to all interested in the industrial application of colonial economic products. Other articles by Bernegau deal with the Togo lemon (*Citrus medica*) and with *Cola acuminata* and *C. vera* seeds.

One of the most important papers in the volume is that by F. Muth on the influence of the nature of the seed-bed on the germination of seeds. Contrary to the opinion prevailing in Germany that, though the nature of the seed-bed is of minor importance, strong filter or blotting paper is the best medium, Muth finds, as a result of many trials of every kind of seed, that blotting paper for most seeds does not provide the best seed-bed. He recommends unglazed white or yellow porcelain dishes. The results of the seed-testing in the Government station in Ireland, of which I have charge (more than 2000 tests being made annually), fully support Muth. Further, we find that for cereals a soil-test, apparently not tried by Muth, gives better results than the porcelain dishes. Brick supplies an illustrated account of the diseases of cocoa, rubber, and other tropical plants of cultivation, and Appel a, now somewhat belated, paper on potato leaf-roll.

The report is one which no one concerned with economic botany should overlook, and reveals the many-sided practical bearings of botany. T. J.

A NEW METHOD IN ANIMAL PSYCHOLOGY.

THOSE who remember the Huxley lecture delivered in 1906 by Prof. Pawlow, in which he complained that the physiology of the sense organs had hitherto suffered from the evil influences of psychology, will turn with interest to a paper entitled "The Method of Pawlow in Animal Psychology," which is contributed to the August number of the *Psychological Bulletin* by Messrs. R. M. Yerkes and S. Morgulis. The method which Prof. Pawlow introduced consists in studying the modifications of the salivary reflex under various mental conditions. By a simple operation a salivary fistula is formed on the outer surface of the cheek of a healthy dog; the wound quickly heals, and the animal suffers no further inconvenience. The flow of saliva under different conditions is studied by collecting it from the fistula and observing its volume and viscidity in given intervals of time. Pawlow calls the salivary reflex "unconditioned" when (as, for instance, on the introduction of food into the mouth) the stimulus naturally and directly calls forth the reflex. On the other hand, a "conditioned" reflex occurs through artificial and indirect causes. Thus, if a sound of constant pitch is produced near the dog on every occasion when food is given, this particular sound (after adequate practice) is sufficient to cause a secretion of saliva in the absence of food. According to Nicolai, the "reflex" thus obtained is a complicated process, the secretion being connected only indirectly with the sound-stimulus by the mediation of the "idea of eating." When once such a conditioned "reflex" has been established, the interest of the experiment consists in seeing to what extent, if at all, the "reflex" is evoked by modifying the stimulus, *e.g.* by varying its pitch, timbre, or loudness, or by including the tone in a chord.

The paper gives a lengthy *résumé* of the study of auditory reactions made in this way by Selionyi, one of Pawlow's pupils. A paper by Orbeli, another of his pupils, also written in Russian, is likewise abstracted in considerable detail. This deals with the visual reactions of the dog. The writer concludes that the "study of conditioned salivary reflexes furnishes no indication that rays of light of different wave-length are received as distinct stimuli by the eye of the dog," although such reflexes "are essentially dependent upon the intensity of the light-stimulus." Nicolai likewise fails to find evidence of colour-vision in the dog. It would, however, be rash to conclude from these experiments that dogs are colour-blind. The dogs mostly used in Pawlow's laboratory were a mixed breed of hunting dogs, and it may well be that in this particular breed colour-differences are very ill attended to. Moreover, it is quite conceivable that when an animal has been trained to salivate, say, to a blue stimulus, a yellow stimulus may also cause salivation, and yet may be clearly distinguished in the dog's consciousness from the blue. This shows the weakness of Pawlow's method and the cautions which are necessary in deducing the mental states of an animal from the study of its salivary secretion. To judge from the list of forty-two papers published (mostly in Russian) by Pawlow and his pupils since 1904, the St. Petersburg school of physiologists has unbounded faith in the possibilities of the method.

THE MESSINA EARTHQUAKE.

THE Messina earthquake of December, 1908, will probably occupy the attention of Italian seismologists for some time to come. In the meantime, Dr. Mario Baratta has published a summary of the results at which he has arrived during an investigation made under the auspices of the Italian Geographical Society. The great shock, he remarks, was not announced by any slight movements in the district chiefly affected. The greater part of this district lies in the Calabrian peninsula, bounded by a line which just includes Palmi, San Procopio, San Stefano, and Pellaro. In Sicily the bounding line includes Faro Superiore, close to the north-eastern corner, and passes a short distance to the west and south of Messina; but, even in this region of maximum devastation, there are small areas within which the buildings appear to have been miraculously preserved.

Excluding Reggio and Messina, where the number of victims is still unknown, the mortality reached a maximum at Cannitello, with a percentage of 42·7; in a few places it ranges from 20 per cent. to 30 per cent., more frequently it lies between 10 per cent. and 20 per cent., while in most places it was less than 10 per cent. Besides the principal meizoseismal area, there are other regions marked by an increase of intensity, such as the well-known zones of Monteleone, La Piana, Ferruzzano, &c., so strongly disturbed in 1905, 1783, and 1907 respectively.

In the chief meizoseismal zone the shock was preceded by a very loud rumbling like the firing of a gun, and the perceptible movement, which occurred in three separate phases, was estimated to last about thirty seconds. The time of the shock within this area is known with considerable accuracy, the clock at the geodynamic observatory of Messina having stopped at 5h. 21m. 30s., or 4h. 21m. 30s. Greenwich mean time. On the Calabrian shores, the sea-waves were greatest at Pellaro, Lazzaro, and Gallico; in Sicily, near Briga, Riposto and Paradiso; they were distinctly perceptible at Malta, and were registered by the tide-gauges at Porto d'Ischia, Naples, Civitavecchia, Porto Corsini, and even in the neighbourhood of Venice.

Dr. Baratta attributes the disastrous results of the recent earthquake chiefly to three causes—the damage resulting from preceding earthquakes, and especially those of 1894, 1905, and 1907; the nature of the rocks on which the houses were built; and the wretched materials used and a system of construction in complete contradiction to the elementary rules that should govern all building in seismic countries. He gives the following scale of foundations, beginning with the worst:—yellow sands, sands and conglomerates in irregular beds, recent alluvia, Miocene sands and conglomerates, limestones and crystalline rocks. The recent earthquake he regards as far inferior in intensity to the first great shock of 1783, which produced permanent changes in the ground and attained a maximum mortality, though occurring in the daytime, of 77 per cent. at Terranova.

PHTHISIS AND INSANITY IN RELATION TO INHERITANCE.

A MEMOIR "On the Inheritance of the Diathesis of Phthisis and Insanity," by Dr. Charles Goring, has been issued by Messrs. Dulau and Co. in the series of Drapers' Company Research Memoirs, emanating from the Department of Applied Mathematics, University College, London. The methods used are similar to those employed by Prof. Pearson in his "First Study of the Statistics of Pulmonary Tuberculosis" and by Mr. Heron in his "First Study of the Statistics of Insanity," but the data are better in one respect, inasmuch as they are based, not on hospital or asylum cases, but upon information obtained respecting the inmates of convict prisons. Whether, however, such a sample can be correctly described as a random sample of the general population, as the author holds, is certainly open to question.

The conclusions reached by Dr. Goring are confirmatory of those previously put forward by Pearson and by Heron; for both phthisis and insanity he finds a very marked correlation between parents and offspring, the coefficients fluctuating round 0·5. In the case of phthisis no evidence is found of infection between husband and wife, the marital correlation being insignificant and negative. When, however, the author states, arguing against the view that the observed correlation between parent and child may be due to infection, that "upon statistical evidence one conclusion alone seems to follow inevitably and may be asserted without reserve. It is that such parental infection, if existent, is relatively inconsiderable, and that almost the whole of the parental association in phthisis represents an inherited predisposition in the child to be infected with the disease of his parents: that the one vital factor in the occurrence of tuberculosis is inheritance," he makes in the last sentence an assertion which it is a little difficult to excuse. To mention only the best known data, he will find in part ii. of each of the last two decennial supplements published by the Registrar-General ample evidence that the mortality from phthisis is five to ten times as great for persons engaged in certain occupations as for persons engaged in others; it is surely idle, with such evidence at hand, to argue that environmental factors are of no importance!

We do not wish to underrate the value of the memoir—the author deserves the thanks of all those interested in the problem for his reduction and discussion of the data—but we think it should be read with caution, as the writer appears insufficiently acquainted with the other evidence bearing on the question. In conclusion, a doubt may be raised whether the most satisfactory method of studying the influence of heredity on phthisis is to deal as a whole with a random sample of the general population. In view of the widely divergent liabilities of different occupations to phthisis, the heterogeneity of the sample may very well unduly increase the correlations observed.

SOME PAPERS ON AMERICAN ZOOLOGY.

THE mammal and bird fauna of Alaska and Yukon territory forms the subject of No. 30 of the "North American Fauna" (U.S. Department of Agriculture). The author, Mr. W. H. Osgood, gives the results of his observations, both on the nature of the country and the fauna, made during three traverses, namely, one through east central Alaska, a second through the Ogilvie Range of the Yukon, and a third along the course of the Macmillan River. The habits, mutual relationships, and range of the different species form the main subject of the biological section, new names being very few. The attention of sportsmen may be directed to certain observations connected with the habits of moose; but, so far as mammals are concerned, the chief interest in this issue is concentrated in the announcement that the pure white bighorn sheep of the Kenai Peninsula, the so-called *Ovis dalli*, passes by imperceptible gradations into the black sheep (*O. stonei*) of the Stikine Valley. For the future these northern wild sheep must be regarded as local races of the Rocky Mountain Bighorn.

Nos. 1701 and 1702 of the Proceedings of the U.S. National Museum are devoted to the description of portions of the collections obtained during the cruise of the *Albatross* in 1906. In the first of these Miss H. Richardson gives an account of the isopod crustaceans collected in the north-west Pacific. In addition to the new Holotelson—a member of the eubranchiate section distinguished by the emargination of the terminal segment of the abdomen—the author describes a very large number of new species, especially in the genus Arcturus.

Fresh-water sponges from the Philippines form the subject of the second paper (No. 1702). The collection was submitted to Dr. Annandale, of the Indian Museum, who refers some of the specimens to *Spongilla philippinensis*, a species described by himself earlier in the present year, and the rest to a new species, *S. microsclerifera*.

In No. 1703 of the same publication Mr. J. P. Moore describes a collection of polychætous annelids dredged last year off the coasts of Labrador, Newfoundland, and Nova Scotia. Most of the specimens came from Labrador, and all are referred to species already known. They serve to confirm the supposition that the Labrador polychætes would prove to belong mainly to Arctic types, with some admixture from a more southern fauna.

STEAM TURBINES.[1]

IN the first lecture it was pointed out that the first practical steam engine was Newcomen's, about the middle of the eighteenth century, and it used about 20 lb. of coal per horse-power hour. James Watt succeeded in reducing this to 5 lb. or 7 lb. of coal per horse-power hour, chiefly through the introduction of the separate condenser, and the Watt engine remained in principle without other than detail improvements until the gradual rise of steam pressure, and consequent extra expansion, caused compound, triple, and finally quadruple expansion engines to be introduced, and as a result the coal bill is now some one-fifteenth of what it was in the time of Newcomen.

It has, however, been found that with reciprocating engines there must be a steam pressure of about 7 lb. per square inch on the low-pressure piston, or otherwise its size and weight become excessive, and also that there is little or no benefit in going to a higher vacuum than about 25".

With the steam turbine, vacua of 28½" or 29", or absolute pressures of from ¾ lb. to ½ lb. per square inch, can be easily utilised, since the difficulty of dealing with large volumes of steam does not occur in the case of the steam turbine as in the case of the reciprocating engine, and it has been found that with the steam turbine the gain due to vacuum goes steadily on up to the highest attainable vacua. Between 25″ and 26″, or 26″ and 27″, there is a gain of about 4 per cent.; a further gain of 5 per cent. is made with the vacuum increased to 28″, and a still further gain of 6 per cent. to 7 per cent. when it is increased to 29″.

---

[1] Abstract of three Cantor lectures delivered before the Royal Society of Arts by Mr. Gerald Stoney, and published in the Journal of the Society for October 8, 15, and 22

This is more easily understood if we consider that the theoretical power to be derived from the steam is almost proportional to the logarithm of the expansions, and thus practically the same power can be obtained working from 400 lb. to 1 lb. absolute, or 28″ vacuum, as from 200 lb. to ½ lb., or 29″ vacuum. In each case there are 400 expansions by pressure, and in each case the theoretical consumption of steam by Clausius' cycle would be about 9·3 lb. per kilowatt hour. With 150° F. superheat this would come down to 8·7 lb., and under the conditions of 200 lb. pressure and 29″ vacuum with 150° F. superheat, 13·2 lb. per kilowatt hour has actually been obtained with an overall efficiency, including the alternator, of about 66 per cent., or 71½ per cent. on the turbine shaft, allowing for the electrical losses. Prof. Ewing, in his book on "The Steam Engine," gives a list of principal results obtained from condensing reciprocating engines, and in no case does the ratio of the consumption of steam by Clausius' cycle, compared with that used per indicated horse-power, exceed 64 per cent. As the ratio of brake horse-power to indicated horse-power is never more than 90 per cent., this means an efficiency at the engine shaft of not more than 58 per cent. When it is remembered that the figure obtained in the case of the turbine was 71½ per cent., and further that the reciprocating engine is unable to take advantage of high vacua, it is easily seen where the advantage of the turbine, especially in large sizes, comes in.

The other advantages were dealt with of absence of vibration, reduced cost of repairs and maintenance, and space occupied, this last being only in some cases one-third or one-fourth of that necessary for reciprocating engines.

In very large sizes, also, it has been found practically impossible to make reciprocating engines satisfactory, and it may not, perhaps, be generally known that one of the reasons which led the Cunard committee to adopt turbines for the great express steamers *Lusitania* and *Mauretania* was the fact that the engineering difficulties of the enormous reciprocating engines required made the problem almost impossible of solution without the use of turbines.

Steam turbines may be divided into two great divisions, single and compound. In the former class there is the De Laval, in which the whole of the expansion is carried out in a single jet, but in order to get efficiency the speed of revolution is so high that gearing has to be resorted to, and this limits this type of turbine to small sizes.

The second class is that universally adopted for all large turbines, in which the expansion of the steam is carried out in stages.

The compound turbine naturally divides itself into two subclasses, those in which the expansion of the steam takes place both in the fixed and moving blades, and those in which it takes place in the fixed blades only. Included in the former class is the Parsons, while the latter contains the Rateau, Zoelly, Curtis, and various others. In the Rateau and Zoelly, which strongly resemble one another, the velocity of the steam at each stage is taken up by a single row of blades mounted on a wheel, and in the Curtis by a wheel having two or more rows of moving blades with guide blades between. There are also various combinations of these, especially those with a Curtis high-pressure part and a Parsons low-pressure, but as yet they have not come largely into use.

A description is then given of the various types of turbine, and also the method of calculating the blading and other particulars, along with some practical rules for their design, and it is shown that, with these limitations, turbines can be constructed with similar stresses and dimensions to give outputs varying as the square of their dimensions and inversely as the square of the speed of revolution.

Now it can be shown that alternators also obey the same rule of varying inversely as the square of the speed, and thus it will be seen that alternators coupled to turbines go up in size together, and that, apart from the trouble there is due to being compelled to have an even number of poles, alternators of the maximum size for that speed have similar turbines attached to them, and thus there is no limit to the size of turbo-alternator. In the case, however, of continuous current dynamos, the output of a dynamo (as it is chiefly limited by commutation conditions which depend principally on the ampere turns on the armature per inch diameter) is practically only proportional to the speed, and it is easily seen that a limit is soon reached where the speed of the turbine is too low for economical conditions.

However, by using tandem dynamos it will be seen that the output is doubled, and this enables tandem turbo-dynamos up to about 4000 kilowatts to be economically built.

In the second lecture various applications of and auxiliaries to the steam turbine were described.

The design of condensers has been especially influenced by the introduction of steam turbines. As has been shown, in the old days of reciprocating engines, the condenser giving 25″ vacuum was quite good enough, but nowadays, on account of the great improvement in economy of steam turbines, with higher vacua, it is common to have between 28″ and 29″.

The maximum vacuum which can be obtained from a condenser is the vacuum due to the temperature of the outlet water, and the closer to this we can get the vacuum actually obtained the better. There are two ways of expressing this difference: one is by pressure and the other is by temperature, and for condenser work the latter is the more convenient. When it is remembered that from about 24″ to 27″ each inch of vacuum makes 4 per cent. difference in the steam consumption of a turbine, between 27″ and 28″ about 5 per cent., and from 28″ to 29″ 6 per cent. or 7 per cent., or that, approximately, 3° F. difference in the temperature of the exhaust means an increase or decrease of about 1 per cent. in steam consumption, it is easily understood how important it is to keep the difference of temperature between the outlet water from the condenser and the temperature due to the vacuum as small as possible. This difference in good modern condensers, when condensing, say, 12 lb. per square foot per hour, can be kept as low as 5° F. or 6° F.

Another way of looking at the efficiency of the condenser is the B.T.U. transmitted per square foot of cooling surface per hour per 1° F. difference of temperature, and this figure can in well-constructed condensers be as high as 1000 to 1200 B.T.U.

It is in connection with the extracting of air thoroughly from the condenser that the greatest improvements have been made of late years, and amongst these dry air pumps and the vacuum augmentor are especially prominent. This latter consists simply of a jet of steam drawing the air and vapour from the condenser and delivering it through a small auxiliary condenser to the air pump, and thus, although the air pump may only produce a vacuum of, say, 27″ or 28″, there may be a vacuum of 28″ to 29″ in the condenser, and in practice this appliance has been found most satisfactory. The effect of using this vacuum augmentor has been in some cases to bring up the conductivity from about 250 or 300 to between 800 and 1000, or to reduce the loss of temperature from some 26° F. to 5° F., a gain in temperature of, say, 21° F., or 7 per cent., in the consumption of the turbine.

When it is remembered that the steam jet of the vacuum augmentor only uses about 0·6 per cent. of the steam used by the turbine, it is easily seen that the gain due to the better vacuum is vastly more than the loss due to the steam jet.

One great field for turbines which has only within the last couple of years come into prominence, although it was patented by Mr. Parsons some years ago, is the use of exhaust turbines, that is, turbines taking steam at atmospheric pressure from reciprocating engines or other machinery, and utilising the power contained in it in an exhaust turbine. When it is remembered that there is as much power in steam working from atmospheric pressure down to a 27″ vacuum as between 150 lb. down to atmospheric pressure, it is easily seen that the power of an existing non-condensing plant can be more than doubled by the simple application of an exhaust steam turbine and condenser. Such installations are now in use all over the country, and from being absolutely a waste product exhaust steam has become a most valuable by-product in many works. In many cases the exhaust steam is intermittent, such as the exhaust steam from a winding engine of a colliery. Such intervals, if not too long, can be bridged over by a thermal accumulator. The principle of thermal storage is itself a comparatively old idea in connection with steam boilers, having been proposed by Druitt Halpin in 1891–2, but the best-known form of accumulator for use in connection with exhaust steam turbines is that of Prof. Rateau, where a tank containing water has the exhaust steam blown through it so that alternately the exhaust steam is partly condensed, and the water in the tank boils, and thus the supply given to the turbine is constant.

In many cases, however, the stops are too long to be bridged over by any form of thermal accumulator, and in such cases what are called "mixed pressure" turbines have been introduced, in which there is a high-pressure part revolving idly when exhaust steam is used, but when the exhaust steam supply fails, by an automatic arrangement this high-pressure part is supplied with live steam, and thus the turbine continues to be driven.

The first applications of the steam turbine to driving machinery were in the driving of electrical machinery, and on land this still continues to be the greatest use for steam turbines, and a full account of turbo-alternators and dynamos is given.

An important development during the past few years has been the application of the steam turbine for driving air compressors. An ordinary steam turbine when driven backwards does not act as an air compressor, but if the blades are suitably shaped it forms a very efficient one, and this fact has led to a large development in the application of steam turbines.

Such turbo-blowing engines are largely used for blast furnaces, the blast pressures required ranging generally from 10 lb. to 16 lb. per square inch.

It may be mentioned that the weight of a turbo-blowing engine complete is 25 tons, and the weight of a reciprocating engine of the same power 430 tons, or seventeen times heavier than the turbine.

For producing pressures higher than 25 lb. per square inch, the design of the blowing engine is usually of the centrifugal type, and consists of a number of centrifugal fans specially constructed to withstand the stresses caused by the high speed of revolution.

In the third lecture an account is given of the greatest development of the steam turbine, that for marine propulsion.

The large and increasing amount of horse-power, and the greater size and speed of the modern engines, tend towards some form which shall be light, capable of perfect balancing, and economical in steam. The marine engine of the piston type does not fulfil these requirements. This led to the well-known *Turbinia* being built, which proved the success of the steam turbine for marine propulsion. After the *Turbinia*, the *Viper* and *Cobra*, torpedo-boat destroyers, followed, but the next great step was the *King Edward*, built in 1902. The arrangement of the turbines was altered considerably from that of the *Turbinia* in order to get increased manœuvring power. Three shafts were still retained, with two screws on the wing shafts and one on the centre shaft, which revolved at rather lower speed; but, instead of all the three turbines being in series, the steam passed first through the centre high-pressure one, and then was divided between two low-pressure turbines, port and starboard. In the same casing as these low-pressure turbines, and at the exhaust end, the stern turbines were incorporated. This gave much better manœuvring power than with the arrangement in the *Turbinia*, as when manœuvring the high-pressure turbine was cut out and steam admitted direct to either or both of the low-pressure turbines or to the astern turbines, thus giving as good manœuvring power as in the case of a twin-screw ship with reciprocating engines.

The success of the *King Edward*, together with that of the *Viper* and *Cobra*, led the Admiralty to have turbines fitted into one of four third-class cruisers, and the vessel chosen was the *Amethyst*. Extensive trials were carried out between her and her sister ship, the *Topaz*, with reciprocating engines, each being 350 feet long and of 3000 tons displacement. The result was that at all speeds above 14 knots the turbine was the more economical, being 15 per cent. better at 18 knots, 31 per cent. better at 20½ knots, and 38 per cent. better at 22·1 knots.

With cross-Channel boats it has been found that the turbine vessels use 25 per cent. less coal per passenger, and travel 2 knots faster, than those with reciprocating engines, and the *Lusitania* has been shown by Sir William White to be 16 per cent. more efficient than the great German reciprocating liners.

The application of the steam turbine to the propulsion of slow-speed ships, that is, ships of below 15 to 18 knots, has up to the present been difficult, owing to the low speed of revolution of the screws making the turbines large and heavy, as well as not economical. This difficulty has now been got over by the use of an arrangement patented by Mr. Parsons some years ago, viz. the combination of reciprocating engines and exhaust turbines, similar to what was described before for land work. Here each utilises the part of the expansion for which it is best suited—the reciprocating engine for the high-pressure part of the range and the turbine for the low-pressure where the volume of steam is large.

It is interesting to note that in the early days of the screw propeller the great difficulty was to make the engines run fast enough for the screw, and spur gearing was adopted in many cases in the first half of the last century. Gearing has been entirely dropped for the last fifty or sixty years, but now the difficulty in many cases is to make the turbine run slow enough for the screw, and once more gearing is being considered so as to make the turbine adaptable for use in slow-speed steamers, which, after all, constitute by far the greater part of the shipping of the world.

The combination system described above does this, but gearing a high-speed turbine to a slow-speed screw would also accomplish what is needed.

Eighty years ago there was nothing but primitive spur gearing, with generally wooden teeth in one member, but now we have steel gears accurately cut by modern machinery, often with helical teeth, and running in oil baths.

At the present date there are about 120 vessels actually on service fitted with turbines, representing about 1,250,000 horse-power, and these comprise practically all the high-speed ships which have been recently built. Some seventy more are under construction, representing another 1,000,000 horse-power, or a total of 2,250,000 horse-power, and the curve of progress as yet shows no sign of saturation.

THE OUTLOOK OF SCIENCE.[1]

PROBABLY there never was a time when the scientific spirit was more active than at the present moment. We see evidence of this on all hands. In the realms of abstract science we have researches dealing with profound questions as to the intimate nature of matter that were not within the sphere of thought only a few years ago. The theories of electrons which are founded on mathematical and physical investigation give us a glimpse into worlds of movement of which those before us had no conception, and of stores of energy that may one day be liberated in the service of mankind. That mysterious agency, electricity, is now seen to be probably at the basis of all phenomena, physical, chemical, vital, and a new interpretation is given of many actions going on all around us. The relation of matter to the circumambient æther also engages the speculations of men of science.

Researches at extremely low temperatures, down near to absolute zero, as carried out by Dewar, are enabling the physicist and chemist to criticise the properties of matter from a new point of view. The microscope, hitherto an instrument used mostly by the biologist, is now employed in the investigation of the molecular structure of metals and other substances, as these are modified by pressure and strain. The phenomena of radio-activity have opened up a new world, and no achievement of science is, to my mind, more wonderful than the way in which a modern physicist can measure the velocity and count the number of inconceivably minute particles that fly off from a morsel of radio-active matter.

---

[1] From an address delivered to the associates and students of the Glasgow and West of Scotland Technical College on October 28 by Prof. John G. McKendrick, F.R.S.

For many purposes the steam engine has been outdistanced. The energy now available from modern engines is much greater than was at one time thought practicable. The best triple-expansion steam engines gave back as mechanical energy only 17 per cent. or 18 per cent. of the energy represented by the combustion of the fuel, the remaining 82 per cent. and 83 per cent. being lost, or, at all events, is mechanically inefficient, as heat. A human muscle gives as mechanical energy 25 per cent. of the energy of the food, but the remaining 75 per cent. of heat is necessary for the life of the muscle, so that, in this aspect, it is superior to the steam engine.

I have often been struck with the wonderful economy of nature. She attains her ends usually by the simplest and most direct method and with the smallest expenditure of matter and energy, and one cannot help thinking that future inventions—I mean inventions during the next two or three centuries—will be in this direction. The electric organ of an electric eel, at rest, may show so small an electromotive force as to require a good galvanometer to detect it, but a nervous impulse from nerve-cells in its spinal cord may suddenly raise a potential of many volts, and this with little heat and with so small an expenditure of matter as to defy the most expert chemist to weigh it. The electric organ is in no sense a storage battery, but rather a contrivance by which electrical energy is liberated at the moment it is required. The fire-flies, the glow-worms, and many deep-sea fishes can produce light without heat and at a cost which would make the price of a wax vesta an extravagant outlay. Plants, possibly aided by micro-organisms, or at all events by ferments (enzymes), can produce alkaloidal substances at a low temperature and by slow processes; but, on the other hand, to produce these synthetically the organic chemist requires all the resources of his laboratory, high temperatures, acids, and other potent agencies. Many other examples might be given of the economy of nature all establishing the truth that the principle of least action holds good everywhere—a principle which some have thought was a greater, at all events a wider, generalisation than that of the conservation of energy.

There is another department of science to which I must refer in this brief survey. I refer to bacteriology, a branch which deals with the life-history of minute organisms that play a very important part in the economy of nature. In the public mind there is a widespread impression that bacteria and other organisms are the enemies of man, but this is far from being the case with the great majority of these humble plants. Of the thousand or fifteen hundred species now known, probably only fifty or so are inimical to men. The others are highly beneficent. Some are engaged in taking nitrogen from the air for the use of the higher plants: others in splitting up complex substances existing in the bodies of dead plants and of dead animals, and in restoring simpler substances to the soil: others purify our rivers and lakes; even the ocean is the theatre of their activities: and others have to do with the varied phenomena of fermentation. A knowledge of the life-history of these microbes has enabled the physician and surgeon not only to do much in the way of preventive medicine, but to benefit mankind in the treatment of many diseases; and, what is probably of even greater interest, we now recognise that the *rôle* played by these living beings is of the greatest importance in many industries. Such are the industries connected with fermentations, brewing, distilling, baking; the processes of the dairy, as in butter-making and cheese-making; and the important industry of tanning or making leather. In those industries and in scientific agriculture the services of microbes are being more and more called to our aid. Bacteriologists can now make pure cultures of micro-organisms that are useful, and practical men may sow these in approximate media where they do their useful work. In this way the soil of the farmer may be enriched, the growth of particular cereals, leguminous plants, and roots may be facilitated, and the products of the dairy may be made more wholesome. There can be no doubt that in the future many industrial processes, such as these of tanning, paper-making, and others, will be improved as we are able to call these humble beings to our assistance. This, I think, is one of the fairy tales of scientific achievement.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—Mr. W. G. Fearnsides has been appointed demonstrator of petrology, and Mr. F. J. M. Stratton assistant in astrophysics.

Mr. E. M. Wellisch has been elected to the Clerk Maxwell scholarship.

The general board of studies recommends that Mr. K. J. J. Mackenzie be appointed as university lecturer in agriculture for five years, and that he receive a stipend of 200*l.* a year, payable out of the agricultural education fund.

Dr. Stein will deliver a lecture in Cambridge on Thursday, January 20, at 5 p.m., on his explorations in Asia.

London.—A new syllabus in chemistry is to come into force at the matriculation examination on and after January, 1911. In the new syllabus greater emphasis is attached to the theoretical basis of the science and to physical phenomena, such as the development of heat in chemical reaction. The general characteristics of the metals, including an elementary study of sodium, calcium, and iron, and their common compounds, are introduced, while the elementary organic chemistry and a part of what was termed the "chemistry of common life" has been taken out of the syllabus.

Oxford.—The news of the impending retirement of Dr. E. B. Tylor, F.R.S., professor of anthropology, will be received with universal regret. It is perhaps not easy for the present generation to realise how much the science of anthropology owes to the unwearied labours of Prof. Tylor, continued for the space of full fifty years. The importance which the subject has now attained among the studies of Oxford is in large measure due to the energy and enthusiasm with which, on his appointment in 1883 as keeper of the university museum, and afterwards as reader and professor, Dr. Tylor threw himself into the work of arousing and maintaining interest in the scientific history of the arts and institutions of mankind. Under his careful management, and with the able help of the curator of the splendid Pitt-Rivers collection, Mr. H. Balfour, and of other younger workers, the study of anthropology in Oxford has during the last quarter of a century been completely transformed. Prof. Tylor's kindliness and geniality have secured to him the affection of a large circle of friends, whose good wishes will follow him into his retirement.

The second annual dinner of the Old Students' Association of the Royal College of Science will be held on Friday, January 7, 1910. Tickets may be obtained from the secretary of the association, Mr. T. L. Humberstone, 3 Selwood Place, South Kensington. Sir Thomas H. Holland, K.C.I.E., F.R.S., has consented to nomination as president of the association for the year 1910, in succession to Mr. H. G. Wells.

Speaking at the Strand School, King's College, on December 10, Sir William White said that it is not putting a narrow or improper meaning on the word "education" to say that it must have relation, in the case of the vast majority of men and women, to their getting a livelihood. An examination which is passed by means of cramming is mischievous. In many cases boys crammed for an examination have obtained for themselves positions for which they are totally unfitted. Some men spoil their lives by cramming for examinations; they take away all the freshness of life by simply accumulating different kinds of knowledge for reproduction in a match against time. On the other hand, there are many excellent men who, directly they get into the examination room, can never do themselves justice. Examinations, therefore, do not always find out the best men; but in the circumstances of the present time it seems impossible to find a substitute.

A Reuter message from Brisbane states that the ceremony of the dedication of Government House buildings as the home of Queensland University was performed on December 10 by Sir W. MacGregor, the Governor of Queensland. Sir W. MacGregor read a message from the King congratulating the people of Queensland and expressing the hope that the enterprise and loyalty which have marked the first fifty years of the existence of Queensland may be an abiding heritage, and that the prosperity of the State will be multiplied abundantly in years to come. The Governor said that he was gratified at participating in a gathering of such importance, establishing as it did the corner-stone of a system of State education. In no other country can the pursuits of professional and economic life be followed to greater advantage than in Queensland, which has an extraordinary multiplicity of resources. The university course includes arts, without unduly encroaching upon more modern developments of direct utility. The plan of the University is an elastic one, and capable of unlimited expansion. Sir W. MacGregor assented, on behalf of the King, to the University Bill, and unveiled a tablet dedicating the building. The gift was accepted on behalf of the people by Mr. Bell, the Speaker of the Legislative Assembly. Speeches were also delivered by Profs. David, of Sydney, and Stirling, of Adelaide Universities. Mr. Kidston announced that 50,000*l.* has been set aside for initial expenditure and 10,000*l.* annually for working expenses, and there will be sixty foundation scholarships.

A recent report to the Middlesex Education Committee by its secretary and inspector of schools provides particulars concerning an experiment in operation in Strassburg on employment bureaux for children of school-leaving age. In Strassburg the education authorities work in conjunction with the labour bureaux and the employers. A card is handed to the child on leaving school, which, when filled up, contains all particulars necessary for intending employers. This information is supplied by the parents, the headmaster, and the medical officer. It is obvious that little can be done without the cooperation of employers of labour. Most Strassburg employers now prefer to engage a boy through the bureau, as they are able at a glance to obtain a fair estimate of his capabilities from trustworthy sources, and are in this way safeguarded from employing one who may be unequal to the work required. When a boy is engaged the date is noted, and a record of his career as an employee is kept by the bureau, and this is of great benefit to future employers. The success of this scheme has justified the experiment. Every year a large percentage of children of both sexes find suitable employment in this way. Parents, employers, teachers, and apprentices all speak highly of the scheme. The bureau does not confine its attention to children only, but deals with adults, and is part of a widely spread system, with branches in many parts of Germany as well as in other European countries, and has enabled the authorities to find employment for a large percentage of applicants. The bureau being in direct telephonic communication with every other centre, an applicant is found work in the shortest possible time. With a complete record of a man's career there is little risk of imposture, and no hesitation is made in advancing the railway fare to his work in other towns when necessary.

The prizes and certificates at the Northampton Polytechnic Institute were distributed on December 10 by Sir John Wolfe-Barry, K.C.B., who in the course of his address spoke of technical education as scientific instruction in the useful arts. It was not, he remarked, until about 1870 that we began to realise that all was not well with the trade of England and with English methods. At that period primary education was at a very low ebb, and scientific education was in the possession of very few. Technical education for the masses was unknown, and was scarcely desired. The late Prince Consort played a prominent part in rousing the country to the necessity of altering its methods and fostering technical education. In 1877 the City and Guilds of London Institute led the way in a systematic manner in developing the new movement. Since they put their hands to the plough they have spent 800,000*l.* of their own property, and are still spending at the rate of from 23,000*l.* to 25,000*l.* a year in developing the movement which they set on foot more than thirty years ago, which has materialised into the Central Technical College at South Kensington, the Finsbury Technical Institute, and their art school at Kennington. Turning to the work of the Northampton Polytechnic Institute, Sir John Wolfe-Barry gave the history of its development from its initiation some fifteen years ago. After referring to the assistance given by the City Parochial Foundation, the Skinners' Company, and the Saddlers' Company, he emphasised the debt which it owes to the London County Council. Dealing specially with the subject of technical optics, he expressed the hope that the much delayed development would be proceeded with before another year had passed, for such development would deal with an important branch of a scientific trade, and a trade in which we ought more than to hold our own with foreign competitors. Returning to the general subject of technical education, he indicated its limitations, and showed how one of its chief objects is to enlarge the army of scientific workers, and thus to enlarge the area from which the leaders and generals of industrial life are to be drawn, tending thus to substitute intelligent methods for the rule of thumb and to make man less and less an animated machine. Technical instruction, he concluded, must follow the abstract sciences, and not attempt to limit them. In the course of the evening the head of the mechanical engineering department, Mr. C. E. Larard, gave a lecture on the twisting of materials to destruction. He directed attention to a remarkable testing machine which has been installed in his department, and embodied in his lecture the results of his researches on the behaviour of various qualities of steel when twisted to destruction. By means of this machine specimens of steel up to $3\frac{1}{2}$ inches in diameter can readily be twisted to destruction.

SOCIETIES AND ACADEMIES.

London.

Geological Society, December 1.—Prof. W. J. Sollas, F.R.S., president, in the chair.—W. G. **Fearnsides**: The Tremadoc slates and associated rocks of south-east Carnarvonshire. Results obtained in making a detailed map of the country about Portmadoc, Tremadoc, and Criccieth in Carnarvonshire, and a description of the stratigraphy of the Cambrian and Ordovician rocks there exposed. The sedimentary series are described in the order of their formation. The succession is tabulated. The folding, cleavage, faulting, and jointing of the rocks are described, and an attempt is made to show some relationship between the stress-phenomena which have produced these structures. The great fault through Penmorfa is interpreted as a thrust-plane hading gently to the north-east. It is supposed to form the lowest sole of the group of thrust-planes which follow the southern margin of the Snowdonian mountain-tract. The well-known pisolitic iron ore of Tremadoc is shown to follow the line of this fault. Direct evidence of overthrusting has been got from a study of the graptolite-bearing Llandeilo rocks of Tyddyndicwm, which have been exposed in two artificial trenches dug for the purpose, and the distribution of the andesitic volcanic series in lines of detached lenticles among the Grey Slates is described as evidence of a similar re-duplication of the newer rock-series of the north-eastern district on a more extended scale. It is noted that the dolerites are (1) unaffected by cleavage and faulting, and (2) have metamorphosed rocks which were already cleaved, cut, and re-duplicated by the thrust-faulting at the time of their intrusion. The Glacial and post-Glacial accumulations are also described in outline.—E. S. **Cobbold**: Some small trilobites from the Cambrian rocks of Comley (Shropshire). Most of the trilobites were obtained during the progress of the excavations referred to in the report of the Geological Excavations Committee of the British Association, read at the Dublin meeting, 1908. The specimens were derived from the Olenellus Limestone of Comley, and from the Grey Limestones which intervene between that horizon and the Conglomeratic Grit, yielding a Paradoxides fauna.—J. B. **Scrivenor**: The rocks of Pulau Ubin and Pulau Nanas (Singapore). Pulau Ubin and Pulau Nanas are islands set in the eastern entrance to the Straits of Johore, and consist of igneous rocks of considerable interest. Pulau Ubin is composed mainly of hornblende-granite, but a pyroxene-bearing microgranite is found also, while the hornblende-granite is cut by rhombic-pyroxene bearing veins and also contains angular masses of rock resembling the veins. Pulau Nanas consists of dacite-tuffs and dacite, which are referred to the Pahang volcanic series, of Carboniferous or Permo-Carboniferous age. The tuffs and lavas have been altered by the adjacent granite of Pulau Ubin, and contain much secondary biotite and hornblende; their most remarkable feature is the presence of fragments of altered granite. The mutual relations of the different rocks are described. The normal granite of Pulau Ubin is hornblende-granite, the age of which is certainly post-Triassic and pre-Eocene, perhaps post-Inferior-Oolite and pre-Cretaceous. Veins of quartz-norite and masses of quartz-biotite-gabbro, and veins and masses of a fine-grained rock which may be described as enstatite-spessartite, are found in the normal granite of Pulau Ubin. A pyroxene-micro-granite and porphyry on Pulau Ubin, and a rock at Changi, having the mineral constitution of an amphibole-vogesite, are described. The dacite-tuffs of Pulau Nanas contain fragments of granite which must be of pre-Carboniferous age, and are referable to the granite of Amboyna. The fragments of granite, and perhaps certain pebbles of schorl-rock, are the only evidence found as yet in the Malay Peninsula of pre-Carboniferous rocks.—J. B. **Scrivenor**: The tourmaline-corundum rocks of Kinta (Federated Malay States). Overlying the limestone on the west side of the Kinta Valley is a thin cap of schists, with which are found certain rocks, the two chief constituents of which are tourmaline and corundum. They are often carbonaceous, and, in the many variations found, white mica, brown mica, pleonaste, rutile, and metallic sulphides occur. The tourmaline-corundum rocks of Kinta consist of varying amounts of tourmaline, corundum, carbon, white mica, spinel, and other minerals. They contain cavities about 6 millimetres in greatest width, generally bordered by a layer of corundum grains, with tourmaline grains on the inside of this border. Sometimes solid bodies similar in size and shape to the cavities occur. Smaller bodies occur, sometimes, but not always, accompanied by the larger cavities and bodies. They consist of tourmaline, of corundum, and of tourmaline and corundum. When both minerals are present the corundum forms a shell to a nucleus of tourmaline. The tourmaline-corundum rocks are associated with other rocks, which lead to the conclusion that the structures described are the result of replacement of the materials of preexisting bodies at the time of extensive granitic intrusions. They also are associated with rocks which point to the original beds having been laid down under conditions similar to those that obtained when the Pahang chert series was deposited. As tourmaline-bearing partings in the limestone at Changkat Pari constitute a case of selective metamorphism, so it is thought that the tourmaline-corundum rocks mark a process of intense metamorphism in beds associated with schists. These beds were probably chert and silicified limestone, both being in many cases carbonaceous. The larger cavities and bodies mentioned are believed to be the result of replacement of oolitic grains. The smaller bodies may be, in part, the result of replacement of the materials forming casts of radiolarian structures.

Mathematical Society, December 9.—Sir W. D. Niven, president, in the chair.—T. H. **Blakesley**: An instrument for the kinematical solution of cubic equations.—A. L. **Dixon**: The eliminant of the equations of four quadric surfaces.

Cambridge.

Philosophical Society, November 22.—Prof. W. Bateson, F.R.S., president, in the chair.—J. C. F. **Fryer**: Aldabra and neighbouring islands.—Prof. Stanley **Gardiner**: Western Indian Ocean.—D. G. **Lillie**: Notes on the larger Cetacea. It is pointed out that whaling stations have been recently established off the shores of Ireland and Scotland which offer exceptional opportunities for a study of the larger Cetacea. The history of the whaling industry is briefly traced, and a short account given of the modern methods of whaling from notes taken during a visit to the Irish station. The paper also contains a note on the occurrence of hairs in whales. Hairs appear to be absent in Odontocetes. The distribution of hairs in two species of Balænoptera is described, and a reason suggested for the occurrence of hairs in the Mystacoceti.—G. N. **Watson**: The continuations of functions defined by generalised hypergeometric series.—L. **Vegard**: Some general properties of mixed solutions.

Manchester.

Literary and Philosophical Society, November 30.—Mr. Francis Jones, president, in the chair.—Prof. E. **Rutherford**: The action of the α rays on glass. The author recently reproduced the conditions under which pleochroic halos, such as have been observed in mica, would be formed, by enclosing a large quantity of radium emanation in a fine capillary tube of soda glass. When looked at under the microscope the walls of the tube were seen to be surrounded by a well-defined halo about 0·4 mm. in depth, which was equivalent to the maximum distance of the α particle from the active matter. This result confirms the correctness of the explanation given by Joly of haloes in mica, as being due to small inclusions of radio-active material.—Dr. B. B. **Boltwood** and Prof. **Rutherford**: Production of helium by radium. After mentioning that Rutherford, Geiger, and Royds had shown that the α particle was an atom of helium, and that Rutherford and Geiger had also calculated, by counting the α particles, that 1 gram of radium in equilibrium should produce 158 cubic mm. of helium per year, the authors state that they have recently made a determination of the rate of production of helium by actually measuring the volume produced. They used a barium-radium salt containing about 200 milligrams of radium, loaned to one of them by the Vienna Academy of Sciences. The experiments gave a result corresponding to the production of helium at the rate of 163 cubic mm. per gram of radium per year. Sir James Dewar last year made systematic measurements which indicated that helium was produced at a constant rate equivalent to 135 cubic mm. per gram of radium per year.—Dr. A. N. **Meldrum**: Development of the atomic theory, i., Berthollet's doctrine of variable proportions. The controversy between Berthollet and Proust at the beginning of the nineteenth century as to whether the composition of chemical substances is variable or not has been greatly misunderstood. The histories of chemistry represent Berthollet as a "person who had preposterous notions" about the composition of chemical substances, and was "deservedly annihilated" by Proust. A study of the period shows that Berthollet's teaching, having easily survived the criticisms of Proust, was refuted by Dalton's teaching, and that the doctrine of fixed proportions was only then put on a sound basis.

Paris.

Academy of Sciences. December 6.—M. Bouchard in the chair.—The number of foreign associates has been increased from eight to twelve.—H. **Poincaré**: Curves traced on algebraic surfaces.—T. **Carpentier**: Remarks on an isothermal barometer invented by the Marquis de Montrichard.—C. **Guichard**: Surfaces such that the tangents to a series of lines of curvature touch a quadric.—D. **Cirera**: The magnetic disturbance of September 25, 1909. Details of observations made at the Observatory of Ebro. —J. Comas **Sola**: *Résumé* of observations of Mars, made at the Fabra Observatory, Barcelona, during the opposition of 1909. These observations were made with the double Mailhat equatorial of 38-cm. aperture, the atmospheric conditions in October being extremely good. The main topographical details of Mars are invariable, but this is not the case with the smaller details. A diagram of a portion of the planet accompanies the paper.—Ch. **Nordmann**: A new approximation in the study of the effective temperatures of the stars. These results are based on the application of Planck's radiation law to the spectrophotometrical measurements described in an earlier paper. The temperatures found range from 2870° for ρ Perseus, 5320° for the sun, to δ Perseus 18,500°, and λ Taurus more than

40,000°.—M. **Maneng**: Observations of a small planet, probably new. The elements have been determined from photographs taken by M. Boinot on October 19 and 23.—M. **Tilho**: The precision of determinations of longitude on land by the chronometer, according to observations by the Niger-Tchad expedition. A comparison of the results obtained for differences of longitude by the telegraph, direct-length measurement, and the chronometer show that the last-named agrees very satisfactorily with the other methods.—Eugène **Fabry**: The order of a Taylor's series.—M. **Galbrun**: The representation of the solution of an equation of finite differences for large values of the variable.—Arnaud **Denjoy**: Completely discontinuous ensembles.—D. **Pompéiu**: Discontinuous singularities of uniform analytical functions.—J. **Haag**: Families of Lamé composed of helicoids.—René **Garnier**: Surfaces of the fourth order which admit of an infinite discontinuous group of birational transformations.—L. **Remy**: The birational transformations of surfaces of the fourth order with doubly isolated points.—M. **Ravigneaux**: The generalisation of the formula of Willis on epicycloidal trains.—Hector **Pécheux**: The electrical properties of steels. Measurements are given of the resistances at various temperatures and thermoelectromotive forces (against copper) of four steels, ranging in quality from very soft to hard.—André **Léauté**: The mathematical study of the heating of a conductor traversed by a very rapid oscillatory discharge.—C. E. **Guye** and V. **Freedericksz**: The internal friction of solids at low temperatures. Studies of the torsion of wires of silver, aluminium, gold, magnesium, iron, and quartz at temperatures between 100° C. and −196° C.—H. **Baubigny**: The estimation of dithionic acid and the dithionates. Accurate results were obtained only by the dry method, fusion with a mixture of alkaline carbonate and nitrate.—Marcel **Delépine**: The chloroiridates and chloroiridites of silver and thallium.—G. D. **Hinrichs**: The calculation of atomic weights: the solution of the equation of condition.—A. **Colson**: The reduction of sodium sulphate by carbon. A mixture of lampblack and sodium sulphate reacts rapidly at 950° C., 70 per cent. of the sulphate being decomposed in twenty minutes.—J. A. **Muller**: The phase rule. A reply to the criticism of M. Boulouch.—G. **Leser**: The two isomeric hexamethylene β-diketones.—H. **Arsandaux**: Contribution to the study of lateritic formations.—A. **Maige**: The formation of heterotypical chromosomes in *Asphodelus microcarpus*.—G. **Perrin**: Fertilisation in the prothallus of *Pteris tremula*.—J. **Dumont**: The layers surrounding earthy particles. Sand grains separated from soil by simple levigation are generally coated with a colloidal layer, removable by solutions of oxalic acid. The amount of this layer is shown to depend on the size of the particles.—G. **Grandidier**: The description of a new bird, *Monias benschi*, from Madagascar.—Louis **Roule**: Amphibians of the genus Euproctus.—B. **Collin**: Preliminary diagnoses of some new or badly known Acinetæ.—L. **Cayeux**: The secondary quartz of the Silurian oolitic iron minerals of France, and its replacement in the lower layers by iron carbonate.

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 16.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Some Quantitative Measurements in Connection with Radio-telegraphy: Dr. J. A. Fleming, F.R.S.—Efficiency of Short Spark Methods of Generating Electrical Oscillations: Dr. W. H. Eccles and A. J. Makower.

LINNEAN SOCIETY, at 8.—Report on the Crustacea Isopoda and Tanaidacea collected by Mr. C. Crossland in the Sudanese Red Sea: Rev. T. R. R. Stebbing, F.R.S.—Pycnogonida from the Red Sea and Indian Ocean collected by Mr. C. Crossland: Prof. G. H. Carpenter.—On a Collection of Blattidæ preserved in Amber from Prussia: R. Shelford.—Isopoda from the Indian Ocean and British East Africa: Rev. T. R. R. Stebbing, F.R.S.—The Bryozoa from Collections made by Mr. C. Crossland, Part II., Cyclostomata, Ctenostomata, Endoprocta: A. W. Waters.

INSTITUTION OF MINING AND METALLURGY, at 8.

FRIDAY, DECEMBER 17.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Mild-steel Tubes in Compression and under Combined Stress: W. Mason.—Compound Stress Experiments: C. A. M. Smith.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Foundation and Construction of Dock Walls: H. T. Tudsbery.

MONDAY, DECEMBER 20.

ROYAL SOCIETY OF ARTS, at 8.—Aëronautics: C. C. Turner.

INSTITUTE OF ACTUARIES, at 5.—On the Mortality of Female Assured Lives, with Graduated Tables deduced from the British Offices' Experience, 1863-1893: C. W. Kenchington.

TUESDAY, DECEMBER 21.

ROYAL STATISTICAL SOCIETY, at 5.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Further discussion*: Railway-Signalling in India: C. W. Hodson.—*Probable Paper*: The Design of Rolling Stock for Smooth-rail Working on Heavy Gradients: F. W. Bach.

THURSDAY, DECEMBER 23, 1909.

THE CAMBRIDGE NATURAL HISTORY.

The Cambridge Natural History. Vol. iv., Crustacea, by G. Smith and the late W. F. R. Weldon; Trilobites, by H. Woods; Introduction to Arachnida, and King-Crabs, by A. E. Shipley; Eurypterida, by H. Woods; Scorpions, Spiders, Mites, Ticks, &c., by C. Warburton; Tardigrada (Water-Bears), by A. E. Shipley; Pentastomida, by A. E. Shipley; Pycnogonida, by Prof. D'Arcy W. Thompson. Pp. xviii+566. (London: Macmillan and Co., Ltd., 1909.) Price 17*s.* net.

WITH the present volume, the last to be issued of the ten volumes forming the Cambridge Natural History, that carefully planned and well-executed work is completed. The editors, Dr. S. F. Harmer and Mr. A. E. Shipley, are to be congratulated upon having brought their enterprise to a satisfactory conclusion, and upon having placed at the disposal of advanced students of zoology, both professional and amateur, an authoritative account of each of the principal phyla of the animal kingdom.

The section on the Crustacea had been entrusted to the late Prof. Weldon, and the one chapter dealing with the Branchiopoda, which he had completed before his death, is so clearly the work of a master-craftsman that it is hardly possible not to feel a sense of regret that he was unable to finish the task so well begun, and not to realise dimly what an original and valuable contribution to crustacean literature his completed work might have been. Prof. Weldon's pupil, Mr. Geoffrey Smith, was placed at a disadvantage in having to continue this work at short notice and under pressure of time, and it was not to be expected that he would be able to carry it on upon the same lines as those on which it had been begun. Where he is speaking of matters with which his own researches have given him knowledge at first hand, Mr. Smith had done excellently. Thus there is a very careful account of the order Anaspidacea, and an even more interesting and suggestive section on the parasitic cirripedes Peltogaster and Sacculina, which infest other Crustacea. Other portions of the section, which are clearly compiled from the literature, are, unfortunately, not so satisfactory, and there is great lack of a due sense of proportion in dealing with many groups. Thus the interesting order Cumacea is dismissed in about a page and a half, and the information which is given is so summarised as to be of little value. It cannot but be a matter for regret, also, that in a work of this character on the Crustacea so little attention has been paid to internal anatomy. It is true that much investigation is still necessary before a really adequate account of the morphology of the internal organs in this group can be compiled, but at the same time a very large literature dealing with the subject already exists which has been only very lightly dealt with.

Mr. Henry Woods contributes to the volume a clear and well-illustrated account of the Trilobites. He takes the view that their affinities are with the Crustacea, more particularly with the Phyllopoda, and recognises sixteen families. He is unable, however, to accept either Salter's classification of the families into four groups, or the modification of that classification proposed by Beecher.

The principal chapters on arachnids are by Mr. Cecil Warburton, who has written a very valuable treatise on this group. Mr. Warburton's work is to be especially commended in that he has done such full justice to all aspects of his subject. The anatomy and morphology of scorpions, spiders, and mites are dealt with authoritatively and with great accuracy of detail, whilst at the same time that side of the subject which results from the work and observations of the field naturalist is treated in an equally satisfactory way. Chapter xiv., dealing with the habits of spiders, is, indeed, one of the most interesting in the whole series of volumes of the Cambridge Natural History. The subject is a fascinating one in itself, and the author has, by a judicious introduction of his own personal observations on familiar British species, given to it an air of reality which adds greatly to the pleasure of the reader and to the value of the information given.

Chapters on the king-crabs (Xiphosura) and on Tardigrada (water-bears) and Pentastomida are added by Dr. A. E. Shipley. With regard to the affinities of the latter group of parasites, in which the structure is obviously much modified, the author does not commit himself to any very definite opinion, but contents himself with referring, in somewhat general terms, to those characters which they possess in common with some arachnids. A useful list is given of all the known species, with their primary and secondary hosts.

The concluding chapter of the volume is by Prof. D'Arcy Thompson, and deals with the Pycnogonida. Prof. Thompson writes with somewhat greater elaboration of literary style than is generally adopted by present-day scientific authors, but whether always with happy results we are inclined to doubt. Thus the chapter opens with this sentence:—

> "Remote, so far as we at present see, from all other Arthropods, while yet manifesting the most patent features of the Arthropod type, the Pycnogons constitute a little group, easily recognised and characterised, abundant and omnipresent in the sea."

The enthusiasm of the last clause of this sentence would, we fear, be somewhat damped by a sudden call to find, say, fifty living specimens in any but some specially favoured locality.

The chapter is, however, taken as a whole, clear and accurate, and is certainly the best account of the pycnogonids available for English students. With regard to classification, Prof. Thompson considers that Decolopoda is probably the most primitive form known, and that Colossendeis is closely allied to it. The Eurycydidæ and Ammotheidæ are allied to Colossendeis, whilst the true position of Rhynchothorax is very doubtful. On the other hand, the Nymphonidæ, in which is included the five-legged Pentanymphon, described by Hodgson from the Antarctic, also show a minimum of degeneration, and must, therefore, also be regarded as primitive, though separated from Decolopoda by many differences. The Pallenidæ are closely allied to the Nymphonidæ. The Phoxichilidiidæ have points of resemblance with the Pallenidæ, and the Pycnogonidæ are probably allied to them. The ideas here expressed as to the relations of the different families have, however, recently been questioned by Carpenter, whose views have received support from Calman. According to these authors, the fifth pair of legs in Decolopoda and in Pentanymphon may possibly represent a comparatively new development and not a primitive character.

MORTALITY TABLES.

The Theory of the Construction of Tables of Mortality and of Similar Statistical Tables in Use by the Actuary. A course of lectures delivered at the Institute of Actuaries, Staple Inn Hall, during the Session 1904–5, by G. F. Hardy. Pp. iii+141. (London: C. and E. Layton, 1909.) Price 7s. 6d.

THIS course of lectures, which was delivered under the auspices of the Institute of Actuaries, deals with the construction of mortality and similar tables which, as the author justly observes in his opening sentence, lie at the very basis of actuarial work. They deal succinctly with familiar methods of graduation, such as the graphic and Woolhouse's difference method, but are for the most part devoted to more modern theories of curve-fitting, and to the application of Makeham's hypothesis in dealing with the somewhat intractable curve which arises from the fact that, with assured lives, the rate of mortality is for several years a function of time that has elapsed since medical examination rather than of age.

It may be remarked that a subject involving much technical mathematical detail cannot be satisfactorily dealt with in the form of lectures. Mr. Hardy's first two lectures deal with methods of graduation which are familiar to most actuaries, and can be suitably presented in this form, but the remaining four lectures contain much original work, which can only be thoroughly understood after careful reading and study. Fortunately, Mr. Hardy appears to have realised the limitations of his medium, and in its present form the work is well suited to the actuarial student.

The publication of this book is of special interest, as a perusal of it shows that modern development in the graduation of tables of mortality has, singularly enough, had its impulse and inspiration from outside the actuarial profession. To Prof. Karl Pearson's original work in the field of biological statistics, actuaries are indebted for the new calculus, which was applied by Mr. Hardy in the graduation of the principal mortality tables compiled from the experience of lives assured in British offices, and published a few years ago. Actuaries, indeed, cannot be said to have taken very readily to the new method, and during the last three years there has been a surprising number of contributions in the Journal of the Institute of Actuaries dealing with the development of those finite difference formulas to which Mr. Hardy devotes only half-a-dozen pages in this book, and which will, we hope, in a few years be considered obsolete.

The most interesting part of the book is that dealing with the Pearsonian frequency curves, and it is suggestive of the exhaustive nature of the work done by Prof. Pearson to find that so original a thinker as Mr. Hardy has practically nothing to add to the information we have already received about this important family of curves. He, in fact, refers the reader to Prof. Pearson's works, and to the treatise of Mr. W. Palin Elderton, for fuller information. The latter work was published only three years ago for the benefit of actuaries, and will, we think, hold the field as the only text-book on the subject for some years. In these circumstances, it may perhaps be regretted that Mr. Hardy has seen fit to re-number the types of curves, as this may easily confuse anyone who finds occasion for reference to both books, or to Pearson's original work, which Elderton follows. The student will also be in difficulty at the outset owing to Mr. Hardy giving the differential equation from which these curves are derived as

$$\frac{1}{y}\cdot\frac{dy}{dx}=\frac{bx-x^2}{a-bx-cx^2},$$

instead of the one to which we are accustomed,

$$\frac{1}{y}\cdot\frac{dy}{dx}=\frac{x+a}{b_0+b_1x+b_2x^2+\ldots},$$

and we may mention that a misprint would appear to have been introduced here, as it does not seem possible to derive Pearson's Type I. from the first-mentioned equation.

It is unfortunate that Mr. Hardy has not illustrated this part of his subject by reference to the chief mortality table, in the graduation of which the method of frequency curves has been employed, and was carried out by himself. When it is remembered that this will now be the standard mortality table for many life-insurance purposes, it seems strange that so favourable an opportunity should have been missed.

In justice, however, to the author, it may be as well to say that, taking into consideration the space at his disposal, he has done wisely in devoting so large a proportion of it to the study of the Makeham curves, in the knowledge and manipulation of which he is so able an exponent. At the second International Congress of Actuaries, one of the most eminent of Continental actuaries stated that, in his opinion, the day had entirely gone past in which Makeham's graduation would be practically applied in the graduation of tables; and it is a singular commentary on this statement that the select annuity and assurance tables of the recent experience have been graduated by the application of the formula in question. In order to prove the importance of this matter to actuaries, it is only necessary to point out that the value of an annuity payable during the joint life of two persons of any age can be found from a table giving the annuity values for two lives of equal age, whereas, in the case of a table graduated on different principles, a large volume would be required.

Mr. Hardy's illustrations of the application of

Makeham's curve to the general population will be of great interest to all statisticians.

The publication of these lectures marks, we hope, a turning-point in actuarial graduation; it means that the study of curve-fitting has now become a part of the curriculum of the actuarial student, and a knowledge of frequency curves must be acquired before the diploma of the Institute is won. This recent development has enormously increased our power of interpreting statistics, and Mr. Hardy will have done actuarial science a great service if this book induces the other members of his profession to follow in his footsteps.

MODERN ORDNANCE.

The Engineering of Ordnance. By Sir A. Trevor Dawson. The Gustave Canet Lecture, delivered at the Twenty-fifth Anniversary Meeting of the Establishment of the Junior Institution of Engineers, at the Hall of the Worshipful Company of Fishmongers, June 30, 1909. Pp. iv+53. (London: Percival Marshall and Co., 1909.) Price 2*s.* 6*d.*

IT is generally understood that progress made in the construction of guns, gun-mountings, explosives, and projectiles during the last half-century far exceeds that made in the preceding five hundred years; but the causes of this great advance, and the methods by which it has been accomplished, are not so well known. In this small book, of little more than fifty pages, the author has summarised the facts in a clear and interesting style, in a fashion perfectly intelligible to ordinary readers. The descriptions of ordnance are assisted by means of a series of excellent illustrations representing ancient weapons as well as the most recent types.

The author is an eminent authority on the subjects of which he treats, and he is a master in the art of exposition. As director in charge of the Ordnance Department of Vickers, Maxim and Co., Sir Trevor Dawson has been able to utilise the valuable training and experience he had previously gained in the Royal Navy, and to play a prominent part in recent advances. The value of the work done by him has just been recognised by a knighthood, and many professional friends will join in congratulating him upon this well-deserved honour. The Junior Institution of Engineers was fortunate in obtaining the services of such a man as their first lecturer and gold medallist under the Canet bequest.

M. Gustave Canet was a most distinguished French ordnance engineer who received his principal training in this country under the late Mr. Joseph Vavasseur, and subsequently did much to advance the design and construction of ordnance in his native country in association with the great firm of Schneider and Co., of Creusot. M. Canet was president of the Institution of Junior Engineers in 1907–8; his death occurred at the close of his term of office, and his family founded a Canet Gold Medal as a memorial in accordance with a wish he had expressed. No fitter tribute to his professional eminence could have been paid than that which the volume under review contains—a tribute from a British ordnance engineer of the first rank to the work which his French collaborateur had done in improving ordnance for both sea and land purposes.

The author has compressed and condensed a considerable mass of material into the modest limits mentioned above, at the same time indicating the great range and variety of the subjects affecting the design of modern ordnance. He has also maintained his sense of proportionate value in dealing with each item. He shows how important have been contributions made by metallurgists, chemists, and mechanical engineers, and how essential has been the work of each. Improvements in steel manufacture lie at the root of advance in gun-construction and the making of projectiles. The chemist has played a great part in these improvements, and has devised much more powerful "propellants" to take the place of gunpowder, as well as high explosives which can be safely fired from guns and be capable of working havoc on an enemy's forces or ships. The mechanical engineer has been no less useful; indeed, it is his lot to utilise all that metallurgists and chemists can do so as to embody their latest discoveries in designs for more powerful and accurate artillery, or in the construction of more efficient gun-mountings. Hydraulic, electric, and pneumatic methods of transmitting and utilising power in connection with ordnance all find a place and use, their relative value and efficiency being differently assessed by different authorities.

Sir Trevor Dawson states the case fairly, and records his own opinions in many instances. For example, what he says in regard to "wire-wound" and "solid-steel" systems of gun-construction is well worth study; and equally so are his remarks on the advantages and disadvantages of hydraulic or electrical power for working and loading heavy guns; or his comparisons of nitro-glycerine and nitro-cellulose powders. All these questions must be studied in the original volume, as limits of space prevent even a summary being given of the author's conclusions. Every reader of the book will gain a clear idea, not merely of the ingenious devices now in ordinary use for loading and working heavy guns or quick-firing guns of moderate size and weight, but of the means by which present practice has been attained. Behind the complete control and apparently easy handling of the largest guns there lies a mass of complicated machinery for the proper maintenance and use of which highly trained staffs are necessary. The "sweet simplicity" which prevailed before steam-power and armour-defence came into use has entirely disappeared, and cannot be restored. One comparison may be mentioned in conclusion. In 1864 the most powerful 12-inch gun was a muzzle loader, twelve calibres in length, weighing about 23·5 tons; its charge of powder weighed 85 lb., the muzzle velocity of the 614 lb. projectile was 1300 feet per second, and it could perforate 16 inches of wrought-iron armour at the muzzle, or 8 inches at the maximum range of 6000 yards. The 12-inch gun of 1909 is a breech-loader, fifty calibres long, weighing nearly 70 tons. Its projectile weighs 850 lb., the muzzle velocity is 3000 feet per second, its perforative power is measured by 52 inches of wrought iron at the muzzle, 37 inches at

6000 yards, and 17·5 inches at 24,000 yards. Readers interested in the subject will find in the book many equally instructive comparisons, illustrating the great strides made during recent years in the engineering of ordnance.

W. H. W.

VEGETABLE PROTEINS.

The Vegetable Proteins. By Dr. Thomas B. Osborne. Pp. xiii+125. With Bibliography. [Monographs on Biochemistry. Edited by Dr. Aders Plimmer and Dr. F. G. Hopkins.] (London: Longmans, Green and Co., 1909.) Price 3*s.* 6*d.* net.

THE extent to which the knowledge of the proteins has increased during the last decade is abundantly witnessed by the fact that this is the fourth in this series of biochemical monographs which is devoted to them. Dr. Osborne is undoubtedly the leading authority on the chemistry of the vegetable proteins, and much of the matter considered in this essay was originally made known by his researches. The vegetable proteins are of importance, not only on their own account, but also because of their analogy to the animal proteins, which are being so closely studied at the present time. For this reason, this monograph will be welcomed by animal physiologists.

The author has chosen to treat the subject broadly, and to give a general discussion of the chemical and physical properties of vegetable proteins rather than to describe the individual proteins. Whilst this method of treatment will commend itself to many, it must not be forgotten that there is nothing fundamental to distinguish vegetable from animal proteins as a whole, and there is a danger of setting up some artificial distinction between the two classes.

A clear distinction is made between the proteins of the plant embryo and the reserve proteins of seeds, which so far have been the materials chiefly examined. The reserve proteins are all very characteristic and yield large proportions of some particular amino-acid when hydrolysed. As Pfeffer has pointed out, they are to be regarded as excretory products, for they can take no further part in metabolism, and are lost to the plant. The reserve proteins are far more stable towards chemical reagents than are the living tissue proteins; this property has enabled them to be more drastically purified than most of the proteins of animal origin.

Perusal of the monograph will very rapidly convince the reader of the great experimental difficulties attending work in this field, partly on account of the great tendency to form colloidal precipitates which are difficult to manipulate, and partly because no absolute methods are at present known which enable one protein to be separated from another.

Although, on the whole, it must be admitted we are only just beginning to gain some insight into the chemical nature of proteins, yet a work of this kind, like the other monographs which have preceded it in the series, is so stimulating, and suggests so many possibilities of research, that it requires no other justification for its issue, and it should be in the hands of every earnest student of biochemistry.

We could have wished the author to have been more exhaustive in his treatment, and to have included, for example, some discussion of Dr. H. T. Brown's recent work. The inter-relationship of the proteins of wheat likewise deserves much fuller discussion.

In conformity with the editors' plan, a bibliography of no fewer than 608 papers, arranged alphabetically according to the authors' names, has been added. The publishers may be congratulated on the improved cover. A further advantage in the style of the series is the possession of the wide margins, which enable the reader to amplify the text by his own notes.

E. F. A.

MORPHOLOGY AND MEDICINE.

Clinical Commentaries deduced from the Morphology of the Human Body. By Prof. Achille De-Giovanni. Translated from the second Italian edition by John Joseph Eyre. Pp. xii+436. (London: Rebman, Limited, 1909.) Price 15*s.* net.

THE object of the author of this work is to lay anew the foundations on which the principles and practice of the physician's art are based. The new foundations are the principles of morphology—morphology as expounded by Haeckel, Gegenbaur, and other great anatomists. Like all enthusiastic reformers, as one may infer from the following passage (p. 206), he has evidently suffered considerably at the hand of his Italian confreres:—

> "The academicians (I call them academicians because, according to their way, they have made known that the epithet of colleague is not suitable)—the academicians will not demean themselves by accepting these stupid things. Then there are those who, posing as reforming geniuses, let fly a smile of compassion, and others who, from the Olympus of the hypercritical criticism of which they seem specialists, qualify these things in the presence of the credulous public as works of magic, because they do not seek to comprehend them."

By way of apology for Prof. De-Giovanni's medical confreres, the reviewer must confess that a full comprehension of these new doctrines is not an easy matter. As in some of the more recent novels of Henry James, one is puzzled to know whether the obscurities are due to a lack of sense on the part of the reader or of the writer. At least, from the following passage in the preface, in which Prof. De-Giovanni explains his purpose—and there are passages equally obscure on every page of the book—it is evident that the translator has found an equal difficulty, and, apparently, has abandoned as hopeless the task of making the meaning of the original clear:—

> "Therefore I think that every clinical investigation should be conducted on the basis of the individuality morphologically verified, for every other verification of the facts and phenomena in relation to doctrine and practice in their turn in every concrete case individualise themselves, or, to speak better, present themselves, not such as they may be according to the data of general biological experience, but such as they must be in the morphological type of the individual under examination."

Instead of speculating on the exact meaning of the passage just cited, it will be more profitable to follow Prof. De-Giovanni into his clinic, attached to the University of Padua—the university where Harvey was taught the anatomy of the heart well-nigh on three centuries ago—and note the manner in which he applies his morphological doctrines to the treatment of disease. He wishes "to establish whether the heart is adequately proportionate to the body or not." He applies the following law, which is given here in italics, as in the original (p. 226):—

> "*If one measures the thickness of the right fist (in left-hand persons of the left), placing the tape-measure on the extremities of the first phalanges of the index and little fingers, which articulate with the respective bones of the metacarpus, and fix the ends of the measure surrounding the joints in such a way that it includes their thickness, one will have the measure of the base of the heart.*"

Prof. De-Giovanni's law has several disadvantages; in the first place, it cannot be applied until the patient is dead, and, in the second, it does not hold true even then. Those who are unaware of Prof. De-Giovanni's researches find, in the manner in which the heart responds to its work, a safe indication of whether it is "adequately proportionate to the body or not."

The scientific value of this book may be judged from the passages which have been cited. It is much to be feared that its doctrines will meet, from English-speaking medical men, the same reception as has been accorded to them by Prof. De-Giovanni's Italian "academicians."

A. K.

ELEMENTARY BOOKS ON BOTANY.

(1) *Pronunciation of Plant Names.* (Reprinted from *The Gardeners' Chronicle.*) Pp. v+94. (London: *The Gardeners' Chronicle*, Ltd., 1909.) Price 1*s.* net.

(2) *Botany.* By Prof. J. Reynolds Green, F.R.S. Pp. 128. (Dent's Scientific Primers.) (London: J. M. Dent and Co., n.d.) Price 1*s.* net.

(3) *Essentials of Botany.* By Joseph Y. Bergen. Pp. ix+380. (Boston, New York, Chicago, and London: Ginn and Co., n.d.) Price 5*s.*

(1) THIS is a distinctly useful little book. Although primarily intended to encourage uniformity of pronunciation on the part of those engaged in horticulture, it will also, in these days of neglect of the classics, repay perusal by the professional botanist. Even the latter is occasionally guilty of a false quantity. To take a single example, one frequently hears Conium pronounced Co′-ni-um, though Co-ni′-um (*cf.* the Greek *κωνειον*) is, of course, more correct. But in some cases the compiler has wisely retained Anglicised pronunciations, even though less strictly correct, in deference to established usage. One is tempted to express the wish that more uniformity could be secured in the pronunciation, not only of plant names, but also of botanical technical terms.

(2) Prof. Green's book will probably prove helpful to school teachers and students who have some previous knowledge of the subject. For such it may tend to broaden their conceptions and offer a new point of view. One of the best features of the book is the rather striking and somewhat novel way in which the general adaptation of the plant-body to its environment is constantly emphasised. For instance, the author points out that the effect of the branching of the plant-body (both shoot and root) is to bring the plant

> "into relationship with as large a portion of the environment as possible. Here is clearly an indication or suggestion of an interchange of material between the two."

But the book is rather seriously marred by a want of accuracy, some carelessness of expression, and a few antiquated views to be found in certain of its portions, particularly those dealing with anatomy, *e.g.* the descriptions of root-structure on pp. 35 *et seq.* In fact, all through the treatment of the physiological is much more satisfactory than that of the anatomical portions. Some of the illustrations, too, leave much to be desired; indeed, in a few cases the figures are badly drawn and inaccurate. Perhaps the worst are Figs. 20, 22, and 30.

(3) Though not without blemishes, "Essentials of Botany" may be characterised as an excellent elementary text-book. It is brightly written, and combines in an attractive manner information with directions for laboratory work. The reading of the book is obviously intended to be accompanied by actual examination of specimens, and throughout the work questions are constantly suggested which the student is left to answer for himself by direct observation. The illustrations are, for the most part, thoroughly good, though in a few cases they are not above criticism. For instance, in Fig. 20 centrosomes are figured (though not named) in a cell from one of the higher plants. Again, the flowers of the willow (Fig. 100) would be improved by the addition of the characteristic nectary.

As many of the plants selected are North American species, the book is naturally more suitable for use in American than in English schools. It may, however, be heartily recommended for use also on this side of the Atlantic, though it is to be regretted that the author did not supplement the use of American plant names by the addition of the Latin names as footnotes. This is only done in some cases (*e.g.* p. 183, &c.).

We thoroughly endorse Dr. Bergen's opinion that ecology (except in the most elementary form), and also the detailed discussion of evolution, are better omitted from the average school curriculum.

OUR BOOK SHELF.

Geology in the Field. The Jubilee Volume of the Geologists' Association (1858–1908). Edited by H. W. Monckton and R. S. Herries. Part i. Pp. iv+209. (London: Edward Stanford, 1909.) Price 5*s.* net.

IN commemoration of their jubilee, which took place on December 17, 1908, the council of the Geologists' Association decided to bring out a volume dealing with the geology of those parts of England and Wales which have been visited by the Association during the course of its excursions. The volume, which promises to attain a much larger size than was expected, is to be issued in four parts, the first of which is now before us. It is a well-printed work of 209 pages, with four plates and thirty-four text-illustrations; and it deals with the district north of the Thames from Oxfordshire to Bedfordshire and the eastern counties. It comprises seven articles, with the following titles: (1) Middlesex and Hertfordshire, by Mr. J. Hopkinson; (2) Essex, by Mr. T. V. Holmes; (3) The Pliocene Deposits of the Eastern Counties, by Mr. F. W. Harmer; (4) The Pleistocene Period in the Eastern Counties, by Mr. Harmer; (5) Cambridgeshire, Bedfordshire, and West Norfolk, by Mr. R. H. Rastall; (6) Buckinghamshire, by Dr. A. Morley Davies; and (7) The Oxford and Banbury District, by Mr. J. A. Douglas.

In the articles relating to the several counties we have admirable summaries of what is known of the local geology, with discussions on some controverted questions, and a good deal of new and original matter, special attention being given in most cases to the localities visited during excursions of the association. Accounts brought up to date are given of the classic sections, such as those near Watford and Bushey, at Ilford, Upminster, and Grays, at Shotover Hill, Aylesbury, and Upware. The Palæolithic gravels of Rickmansworth, and the derived sarsen stones lately found there, are illustrated in photographic plates; the Hertfordshire Bourne and the Colne swallow-holes near South Mimms; the Dene-holes of Essex; the physiography of the Cambridge area; the relations of the Jurassic and Cretaceous formations, and of the Shotover Sands and Lower Greensand, are among the many topics discussed, apart from the more particular descriptions of the strata and their fossils. The vagaries of modern palæontological nomenclature are noticeable in different articles, as in the case of *Ammonites varians* (p. 4) and *Schloenbachia varians* (p. 168), to say nothing of some other names, the changes in which form the most serious stumbling-block to the student.

The subject of glaciation is dealt with in several of the articles, and more fully in that by Mr. Harmer on the East Anglian Boulder-clays. His essay, illustrated by two maps showing the distribution of the Drifts and the direction of movement of the ice-sheets, is in itself an important contribution to the advancement of science.

The work will thus be of great practical value to the field-student, and it must be consulted by everyone interested in the progress of geology in this country. At the same time, for historical purposes, the original records of excursions published in the Proceedings of the association must not be neglected.

The Writers' and Artists' Year Book, 1910. Pp. viii+127. (London: A. and C. Black.) Price 1*s*. net.
The Englishwoman's Year Book and Directory, 1910. Edited by G. E. Mitton. Pp. xxvi+382. (London: A. and C. Black.) Price 2*s*. 6*d*. net.
Hazell's Annual for 1910. Edited by Hammond Hall. Pp. lxiii+608. (London: Hazell, Watson and Viney, Ltd.) Price 3*s*. 6*d*. net.

IT would be difficult to select for the busy man a more useful set of works of reference than the new issues of the five annual publications under notice. Each one of them is so well known that it is sufficient in every case to say that, not only has there been no diminution of accuracy and interest, but the various editors have all succeeded in adding to the completeness of the books entrusted to their care.

The long obituary at the beginning of the book, and the addition of some fifty pages to "Who's Who," serve to indicate that there have been material changes made in the new issue. "Who's Who Year Book" continues to be an indispensable supplement to the larger work, to which, indeed, it is a really useful key.

Writers, artists, and photographers will find in the third periodical information which it is difficult to obtain elsewhere.

The volume specially intended for women has been revised very thoroughly. Full information is provided concerning the part now taken by women in professional and other work, and the book may be recommended especially to schoolmistresses and parents desirous of finding suitable avocations for girls leaving secondary and other schools.

Among the new features of "Hazell's Annual" may be mentioned the introduction of signed articles. For example, Sir Oliver Lodge, F.R.S., contributes an article on the new physics, Sir Hiram Maxim writes on the evolution of the flying machine, and Mr. C. C. Turner on aërial navigation in 1909.

The New Physics: Sound. By Joseph Battell. Pp. xvi+274+xlvii. (Middlebury, Vt., U.S.A.: The American Publishing Co.; London: A. F. Bird, 1909.) Price 6*s*. 6*d*. net.

VERY few pages of this new treatment of physics need be read before we reach the conclusion that "the old is better." Mr. Battell's object in writing this book is to give "a condensed but complete exposure of the errors in the present theory of sound." He has been "for years opposed to all undulatory theories, as at variance with the fundamental principles of creation, and otherwise not only entirely, but very foolishly, erroneous," and while anxious to give every credit to such men as Koenig and Helmholtz, he comes to the rescue of truth with a book to prove that "sound, like light and odour, is composed of infinitesimal particles of matter." It is really extraordinary how such an effort as this can secure a publisher. No matter where a reader begins, whether at the beginning, the middle, or the end, the result is the same; it is impossible to interpret the author's meaning. Here and there, it is true, there are a few intelligible sentences, but in the main they are obscure and apparently unconnected with what precedes and follows. As an example of this we may quote the following, and leave it to the reader to gather what information he can.

"That light is made by bodies made to make it, as the sun or a lamp; or odour by things made to make it, as a sweet pea or water lily,—that is, by things having light-making or odour-making machinery, and that they can make no other light or odours than those they were made to make, or have the machinery to make,—is no more true, than that nothing can make Sound unless made to make it, or any sound except what it was made to make, and that means any unless it has the machinery to make it."

The author is, without doubt, ingenious in his way of making his particles submit to his theory. Perhaps this results from his acquaintance with horse-rearing. (It should be mentioned that among Mr. Battell's other publications are several volumes of the "American Stallion Register.") For instance, in order to account for the fact that sound is not propagated in a vacuum—at first sight a difficult thing to do on a corpuscular theory—the author naïvely suggests that the reason is the same as that which makes birds unable to fly without air.

Those who have read Mr. Battell's previous scientific work, "Ellen, or Whisperings of an Old Pine," will find this volume equally amusing, and from that point of view the book is, perhaps, worth its price; but those buying it in the expectation of a reasoned text-book for the study of physics will be disappointed.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Function of Reissner's Fibre and the Ependymal Groove.

THANKS mainly to the investigations of Porter E. Sargent, Reissner's fibre is now known to occur throughout the vertebrate series from the lamprey upwards. Not long ago Mr. G. E. Nicholls directed attention in these columns to its occurrence in the frog, and Sir Victor Horsley (*Brain*, vol. xxxi., 1908) has recently shown that it occurs in monkeys (Macacus). I have myself already described it in Geotria, and have lately observed it in the tuatara and in the cat. Its position and relations are remarkably constant. Commencing beneath the posterior commissure, it extends backwards to the hinder extremity of the spinal cord, lying, at any rate for the greater part of its length, quite free in the iter, the fourth ventricle, and the canalis centralis. Anteriorly it breaks up into very slender fibrils, which are attached to the columnar epithelium of the ependymal groove.

The ependymal groove, though its existence has been strangely ignored by most observers, also occurs throughout the vertebrate series from cyclostomes to mammals. It is found typically as a deep longitudinal furrow on the ventral aspect of the posterior commissure, lined by high columnar epithelium, very different in appearance from that which lines the greater part of the brain-cavity. In this highly specialised condition I have observed it in the lamprey, the tuatara, and the cat. I suggested some years ago, in the case of the lamprey, before the connection of this structure with Reissner's fibre was known, that it might aid in the circulation of the cerebro-spinal fluid, by means of cilia which I thought I had detected on the epithelial cells. Whether this be so or not, I now think that the ependymal groove may have another, and perhaps more important function as an intra-cerebral sense-organ.

Sargent, as is well known, has interpreted Reissner's fibre as a nervous structure which serves for the "short-circuiting" of motor (optic) reflexes, and he regards the epithelium of the ependymal groove merely as an attachment plate for the fibre. This seems to me hardly a sufficient explanation of the existence of such a highly differentiated organ.

The nervous nature of Reissner's fibre is very far from having been demonstrated, and though I was formerly led to agree with Sargent's opinion on this subject, I can do so no longer. Sir Victor Horsley and Dr. McNalty (*loc. cit.*) have shown that electrolytic lesions do not cause any degenerative changes in Reissner's fibre such as would be expected if it were a nerve-bundle, and this result is, of course, totally opposed to that of Sargent's earlier experiments, by which he endeavoured to establish the truth of the optic reflex theory. On the other hand, there is a certain amount of evidence to show that Reissner's fibre is highly elastic, and therefore more of the nature of connective tissue. Thus it is often found that when the spinal cord has been cut across, the fibre has "sprung" and twisted itself into a knot or gnarl in some part of the brain-cavity. This seems to indicate that the fibre in life is under considerable tension. My colleague, Mr. Nicholls, who has for some time past been working at Reissner's fibre in this laboratory, will, I hope, bring forward some further evidence on this head very shortly.

I now wish to suggest, for the consideration of physiologists, that Reissner's fibre and the epithelium of the ependymal groove may form part of an apparatus for regulating flexure of the body. Any such flexure would, it appears to me, tend to alter the tension of Reissner's fibre, and thereby exert a mechanical stimulus upon the cells of the ependymal groove to which it is attached. We may suppose that the stimulus received by these sensory cells is transmitted to appropriate nerve-cells in the brain, and that the deviations of the long axis of the body from the normal position may possibly be regulated by reflex action. We may compare the function of the semicircular canals of vertebrates; also that of the "statocysts" of many invertebrates, which serve, by means of mechanical stimuli due to the action of gravity, automatically to regulate the orientation of the body.

The position of Reissner's fibre, entirely enclosed within the brain and spinal cord, renders it extremely difficult to perform any experiments to test the truth of this hypothesis, but I hope that the ingenuity of experimental physiologists may overcome even such a formidable obstacle as this.

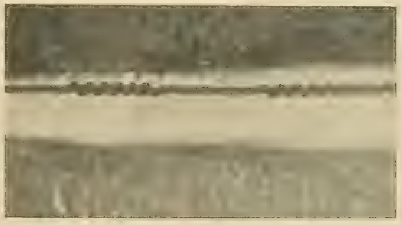
ARTHUR DENDY.
Zoological Department, King's College,
Strand, W.C.

WITH reference to Prof. Dendy's remarks on Reissner's fibre and the suggestion that he puts forward as to its function, I may perhaps be permitted to add a few words.

Of the preformed nature and of the universal occurrence of the fibre throughout the vertebrate series there can remain, I think, no possible doubt.

During the past two years in which I have been engaged in investigating this structure I have examined sections of the brains of a large number of specimens of more than five-and-twenty different genera taken at random from all the great classes of vertebrates, and in *no case* have I failed to find the fibre in properly fixed material. Any of the commonly employed fixing reagents may be used, but it is essential that the material shall be fixed immediately after death.

I have been greatly impressed with the extraordinary elasticity of the fibre, which in life appears normally to be under considerable tension, so that if it be severed in the fresh state the free ends recoil sharply. In one case, where in removing the brain of a toad the fibre was accidentally snapped, so considerable was this recoil that, as subsequent examination of the sections revealed, the free end of the fibre sprang forward into the cavity of the fore-brain, the thin roof of which it actually perforated. Another striking instance of this same character is furnished in certain sections of the terminal portion of the spinal cord of the lamprey, a photomicrograph of which, kindly taken for me by Mr. R. W. H. Row, is here reproduced.



Photomicrograph of a section of the terminal portion of the spinal cord of the lamprey. ×600.

In this case the cord was severed when fixation was only partially effected, and a sudden recoil having been prevented by the partial fixation, the fibre was withdrawn backwards towards its attached end by a more gradual retraction that resulted in the production of a number (twenty-nine) of close coils, two of which appear in the photograph.

From these and other facts I am persuaded that the structure is *not* a nerve, but rather an elastic rod with a merely mechanical function, and to my mind the suggestion Prof. Dendy puts forward as to its function is quite a reasonably probable one.

Geo. E. Nicholls.

King's College, December 17.

Nitrogen-fixing Bacteria and Non-Leguminous Plants.

I regret that owing to Mr. A. D. Hall's letter of July 12 (Nature, July 22) appearing during vacation, I had not an opportunity of seeing it until my return to college at the commencement of term. I trust that, in spite of the long delay, I may yet be allowed to reply to some of Mr. Hall's questions.

Mr. Hall commences by stating that my conclusions are based "on experiments to show that Pseudomonas, the bacterium associated with the leguminous plants, will fix more nitrogen, &c." This is not correct, for it is definitely stated in the abstract that both the Pseudomonas and the Azotobacter used for the nitrogen determination results quoted were obtained from a non-leguminous plant—the root tubercles of Cycas.

There are four non-leguminous plants possessing root tubercles which contain nitrogen-fixing organisms. In all four a species or variety of Pseudomonas is present, but in Cycas only is Pseudomonas found living outside the cortical cells, in the algal zone, and in Cycas only is Pseudomonas found in association with Azotobacter. As stated in my paper, the nitrogen determinations quoted had reference only to these organisms from Cycas, and were made in order to determine to what extent, if any, Cycas *Azotobacter* assisted Cycas *Pseudomonas* in assimilating free nitrogen.

"Pseudomonas, the bacterium associated with the leguminous plants," and the use of "a reasonably active culture" of Azotobacter, to quote Mr. Hall, had nothing to do with the determination experiments. On what grounds, then, does Mr. Hall state that "the only conclusion that could be drawn from Prof. Bottomley's figures would be that Pseudomonas injuriously affects the power of Azotobacter to fix nitrogen"? Naturally, a determination of the amount of nitrogen fixed by the Azotobacter alone was made (for Mr. Hall's information I may say that it was very small, —0·56 mgr.), but as the immediate object of the experiment was to determine the effect of Cycas *Azotobacter* on Cycas *Pseudomonas*, it was not thought necessary to quote the figures for Cycas *Azotobacter* alone, especially as this will be dealt with in a future paper.

Again, when speaking of the experiments with oats, Mr. Hall says that the mean error of ±10 per cent. found in Rothamsted experiments "would more than cover the differences observed by Prof. Bottomley's experiment with oats." The figures given for oats are:—average weight per plant, untreated, 0·42 grm.; treated, 0·74 grm.; increase, 0·32 grm., or 76 per cent. Surely Mr. Hall cannot have read the abstract carefully or he would not have stated that a mean error of ±10 per cent. more than covers an increase of 76 per cent.! As regards probable experimental error, the abstract states that the oats were "grown in sand, dressed with phosphates, potash and lime." Why, then, should Mr. Hall assume that they were grown "in soil which presumably already contains both organisms"?

As regards the field experiment with barley, duplicate samples were not taken from different parts of the untreated plot, but the total yields from treated and untreated plots were kept separate, and the treated showed an increase of 13·6 per cent. The sample for estimation of nitrogen content was taken from the bulk in each case.

The treated bulbs gave an increased yield of 18·6 per cent. They were not selected as being specially "suitable for experiments on nutrition," but to determine the effect of the mixed culture of bacteria on a totally different kind of plant from any of the other experiments. The bulbs were already planted when the experiment commenced, hence the original weight of the bulbs is not available. As, however, the bed contained 500 bulbs, and was divided into two equal halves with 250 bulbs in each, one may assume that the original weight in each half was approximately equal.

As regards the culture solution "being a considerable factor in any beneficial effect experienced," it is difficult to comprehend how 4½ grs. potassium phosphate and ½ gr. magnesium sulphate dissolved in a gallon of water for the culture solution, and this afterwards diluted with fifty gallons of water before applying, could possibly produce any appreciable effect on growing crops. Assuming that the bacteria had not used up any of the culture salts in their growth to produce the culture solution, can one imagine any benefit to plants by watering them with a solution containing 1/50,000 part of potassium phosphate and 1/450,000 part magnesium sulphate?

Mr. Hall appears to consider his questions "somewhat critical." True and fair criticism is always welcome in scientific investigation, for it is only thus that one can get at the truth of things, but misstatements of fact or misrepresentations of results exceed the bounds of criticism. So far as Mr. Hall correctly states the experiments and results given, one welcomes his criticisms.

W. B. Bottomley.

King's College, Strand, W.C.,
November 25.

In Prof. Bottomley's paper in the Proceedings of the Royal Society I cannot read that he makes any claim that the Pseudomonas and the Azotobacter he isolated from Cycas were in any way different in kind from the usual forms of these organisms. When I used the expression "Pseudomonas, the bacterium associated with leguminous plants," it was as a sort of explanatory label for the lay reader, but if it has confused the issue at all I would still repeat my former criticism on Prof. Bottomley's basis that the Pseudomonas and Azotobacter he used are special and unlike all others. The question was if "the association gave an increased power of assimilating free nitrogen," and Prof. Bottomley's figures are:—

Control...	0·48 mgm. nitrogen
Pseudomonas alone	0·91 ,, ,,
Pseudomonas + Azotobacter ...	1·24 ,, ,,

and I asked if the action of Azotobacter alone ought not also to be known before any answer is possible. Prof. Bottomley now tells us that Azotobacter alone fixes 0·56 mgm., so that I still conclude that Pseudomonas and Azotobacter together (1·24) are less effective than when grown separately (0·91+0·56), were I not more inclined to think that all the differences are within the limits of experimental error.

To pass to the experiments with plants, by an error which the context rendered sufficiently obvious I wrote "oats" instead of barley when dealing with Prof. Bottomley's first-quoted experiment with soil. The oat experiment is beside the point; it only demonstrates fixation of nitrogen by Azotobacter and Pseudomonas—a fact on which we are all agreed; but when Prof. Bottomley claims increased crop production due to inoculation with the two organisms in the open ground, we do want the means of judging what weight to attach to the results. He gives for the first barley experiment a gain of 13·6 per cent.; in barley 2 the increase cannot be estimated; the Galtonia experiment shows 18·6 per cent. increase, the parsnips 21·7 per cent. Such percentage differences are not outside the limits of error for a single plot experiment worked on a large scale with every condition in favour of accuracy; when they are differences between lots of 250 bulbs or 68 parsnips I have no hesitation in regarding them as without any significance whatever. I have just had pulled and weighed two lots of fifty successive roots of mangolds growing side by side in neighbouring rows on the same plot, inside rows perfectly similar to the eye and on a very uniform plot, yet one lot weighed 220 lb., the other lot 176 lb., a difference of 25 per cent. The assistant who gathered the roots was quite unaware of the question involved; his instructions were to begin inside the plot and take fifty consecutive roots along a row, then another fifty roots alongside; the difference in the weights merely represents the error of random sampling when numbers are small.

Prof. Bottomley is very scornful over my suggestion that the nutrient salts in the bacterial culture may have brought about an increase in yield, but if it is easy to represent their quantity as small to the verge of ridicule, exactly the same argument might be turned against the bacteria he added. No factor should be neglected to equalise the conditions of the controls and the treated plots. I can give Prof. Bottomley examples in which the nutrient salts accompanying a bacterial inoculation have not been negligible in their effects.

I put my questions to Prof. Bottomley because he does not seem to recognise how large an experimental error he must expect; the conclusions he reaches are of such importance as to demand a more serious body of evidence than the specially selected cases he has put before us.

A. D. Hall.

The Rothamsted Experimental Station, December 13.

Positions of Birds' Nests in Hedges.

What has puzzled Lieut.-Colonel Walsh (Nature, December 16) may be referred to the law of protective devices on the part of birds, and I may say that his facts have been long familiar to other field naturalists and myself. I do not think that the direction north-south or east-west has anything to do with the selection of the nest site. If, at this season of the year, hedges are examined, even very careful "bird boys" and men will be astonished at a much larger number of nests than they observed in summer. If an explored hedge skirts on one side a public road, an "occupation" road, or right-of-way paths, it will be generally found that the nests are on the field side of the hedge, and, therefore, when looked for from the other side, much more difficult to discover than if they were placed on the road or pathway side. In cases where the hedge divides a field from a plantation, the nests are invariably on the plantation side. I knew that very well when I was a boy "nester," and was struck with it only a few days ago on examining a long stretch of hedge-fencing from a semi-public road near my home. However, there may be some esoteric law of bird-life in what Lieut.-Colonel Walsh says. Certainly his facts are most interesting.

G. W. Murdoch.

Woodbine House, Bentham, Yorkshire,
December 17.

RADIUM AND CANCER.

The *Revue générale des Sciences* of November 30 contains a lengthy and important article by Dr. Louis Wickham on the therapeutic action of radium on cancer, based upon observations made on 1200 patients suffering from tumours, half of which are stated to have been malignant. Dr. Wickham himself has demonstrated recently in London and in Belfast the nature of the results he has obtained, and full reports are available in the Proceedings of the Royal Society of Medicine and in the *British Medical Journal.* Therefore there is no need to reproduce the details of the article. The illustrations in the *Revue générale des Sciences* are even more startling than those which have appeared in the English journals cited. The appearances presented before and after treatment are such as will, almost surely, carry conviction to all laymen, whether healthy or suffering from cancer, that radium can cure the disease. But Dr. Wickham does not write in a corresponding spirit of optimism. Indeed, the only note of triumph is the phrase "It is delightful to think that the whole evolution of radiotherapy (the marvellous discovery of radium by P. Curie and Mme. Curie, the construction of perfected apparatus, therapeutical applications) is almost entirely French." No one may grudge this full measure of recognition to the advances made possible in Paris, on the biological action of radium, by collaboration between laboratories of physics, chemistry, and pathology. Not the least measure of praise is due to Dr. Wickham himself, both for his initiative and for his achievements.

Persons who possess an intimate knowledge of the clinical course and pathology of cancer will be less impressed by the pictures of cured cases than by what Dr. Wickham writes and what he omits to refer to. The evidence of diagnosis and of microscopical structure is imperfect. The duration of the period of benefit after treatment, as well as the ultimate fate of the patients, are the criteria by which the success of surgery is measured; but the evidence advanced in Paris falls short of good standards in both respects. Dr. Wickham lays no claim to successful treatment of secondary deposits; he says severe cases ought only to be treated when the surgeon can do nothing, and that it is too early yet to say if radium is the means which ought always to be employed. A warning is given of the necessity for caution in appraising the value of any new treatment, and, above all, of the necessity of avoiding the risk of depriving patients of other treatment which has proved itself superior, especially of surgery.

The results obtained in Paris have attracted the attention of the world. The hopes they have aroused have awakened yet greater expectations for the future, when larger quantities of radium shall be available, and the technique better mastered. Meantime, notwithstanding Dr. Wickham's caution, the writer considers a further note of warning is necessary. All that is claimed for radium is a beneficial action when applied directly to primary growths. Secondary growths inaccessible to direct surgical removal are inaccessible to radium in consequence of the restricted penetration of the rays. Whether or not means will be devised for attacking deep secondary deposits—the very site of which it may be impossible to determine—remains to be seen. The actual injection of emanation solution has met with no success. Nor is the evidence that radium has a marked elective action for cancer tissue so strong, at present, as to arouse any great hopes from more efficacious means of flooding the body with radio-activity. In short, radium does not appear to be nature's remedy for cancer, but an empirical remedy with the same shortcomings as all other such in the case of cancer, in that the local condition alone is attacked and the constitutional conditions are unassailable.

That the body can generate powers of its own, leading to constitutional changes which enable it to deal effectively with cancer, has been abundantly demonstrated by recent experiment. In given circumstances, 100 per cent. of animals bearing transplanted tumours can cure themselves. The facts ascertained show that the natural forces of the body can cope both with secondary deposits and with primary growths. Though this process of natural cure is not, and may not speedily, be elucidated, still, it is not too sanguine an expectation to anticipate that ultimately it will be. The means for checking the ravages of cancer will be found, not by searching the surface of the earth for a vegetable remedy, nor the bowels of the earth for a mineral one, but by following the definite clue, that in the living body itself forces can be elicited which effectively combat the disease. Until that goal shall be attained, when surgery fails or is unavailable, relief may be sought, but cannot be guaranteed, by resorting to treatment with radium, the full possibilities of which are not yet developed, even in Paris.

E. F. B.

THE GREAT WALL OF CHINA.[1]

IT is two thousand years since Chi-Hwangti established his fame by building the Great Wall. Dr. Geil, in the preface to his book, suggests that after so long an interval we remain ignorant of the features of this greatest of all mural ramparts. "There is a Great Wall of China; so much the geographers tell everybody, but they do not make it clear whether it is built of China; or why it is, or how long it is, or how long it has been." We must remind the author that accurate details concerning the wall have been available for at least two centuries. The Jesuit missionaries under the auspices of the Emperor Kang-hi surveyed the wall from the eastern seaboard to the desert of Turkestan. Its course was set down on their map, published in 1718, the first authentic map of the Empire. This was accompanied by a narrative of their survey, giving an account of the wall, its measurements, its length, and the material used in building. Later geographers followed.

The work done, however, by previous travellers need not detract from the merit of the journey made by Dr. Geil. His route lay over one thousand miles in a very rough country, and among people who are not given to welcoming the stranger at their gate, yet the author seems to have covered the ground rapidly, and to have enjoyed immunity from the delays, discomforts, and accidents that impede the progress of the explorer in eastern Asia. He must be congratulated also on securing an admirable series of photographs to illustrate his volume. Taken alone, they supply a valuable pictorial representation of this wonderful barrier, affording evidence of the skill of the builders who at that early period and with the most primitive appliances overcame engineering difficulties that would prove formidable in our own day with all the facilities afforded by science.

Dr. Stein has recently discovered that the wall extends much further west than was previously known, along a desert track in Turkestan, hitherto unexplored. He also found documentary evidence to show that part of this western extension was erected two centuries B.C., during the reign of Chi-Hwangti.

Dr. Geil gives an account of the life and work of Chi-Hwangti at some length, whom he calls "Chin."[2] He was a reformer who built the Great Wall to shut out the Huns, extended and consolidated the Empire, made highways to facilitate intercommunication, and was a promoter of agriculture and industry. He was a prince of hustlers, with an eye to national development and the filling of his treasury. He was a man of boundless ambition and fantastic wickedness. In order that he might pose, and be handed down to posterity, as first Emperor of China, he burnt the classic writings and ancient chronicles of the Empire, and put to death more than four hundred followers of Confucius, an act which earned for him the lasting hatred of the literati. The building of the wall, his greatest work, was accomplished by forced labour, and the builders, under pain of death, had either to give their unremitting toil or be built into the wall as part of the material for their country's defence. "Chin" was an economist.

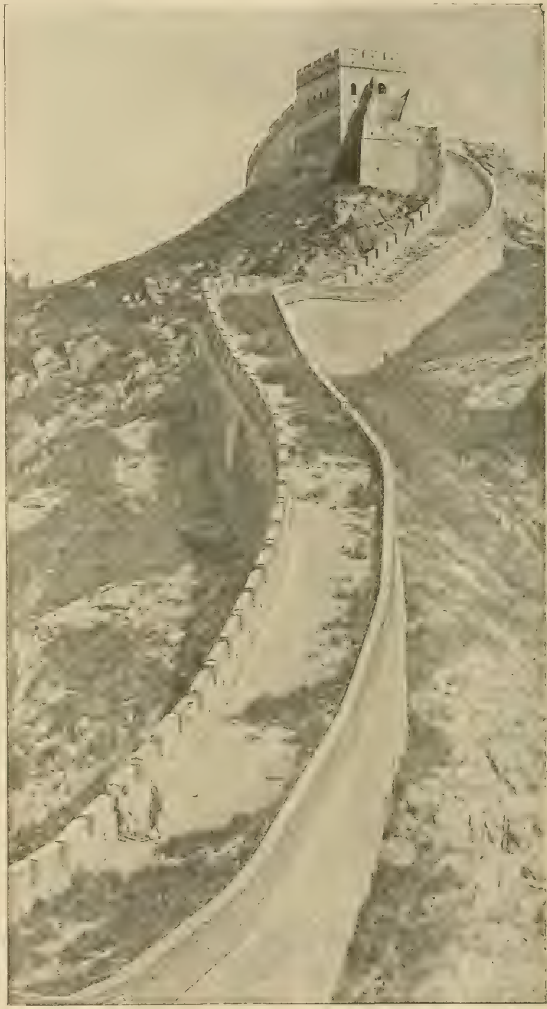


Photo. by H. G. Ponting.

FIG. 1.—The Great Wall ascending a Steep Declivity near the Nankow Pass. From "The Great Wall of China."

---

[1] "The Great Wall of China." By Dr. William Edgar Geil. Pp. xviii+351. (London: John Murray, 1909.) Price 21s. net.

[2] Chi-Hwangti, Second Emperor of the Tsin dynasty.

The author admires this potentate's pushfulness, and would welcome the advent of such another ruler, or a reincarnation of Chin, to awaken China from her sleep of ages—that is, Chin modernised and shorn of his wickedness. He may not have long to wait. Dr. Geil's historical notes on the life and doings of this famous emperor are written with force and an entertaining display of humour. But, after all, the manner of building, it is a sordid tale of suffering, of which the wall is a lasting memorial.

Dr. Geil pauses at intervals in his journey to copy ancient tablets of local wall interest, and to consider, at length, the myths and superstitions of the Chinese, and the condition of the world coeval with Chin the hero. The rise and progress of Genghis Khan, "the red raider," who eventually pierced the barrier and conquered China, are dealt with. He is described as "A man of elemental fury beyond the sweep of twentieth century imagination," whose bloody career did not end until he had slain as many people as now live in all New England, New York, and Pennsylvania—a monster of cruelty. Yet his grandson, Kublai Khan, who came to the throne, proved one of the most enlightened monarchs known to Chinese history. He excavated the Grand Canal, and extended his sway as far as Moscow and the Levant. Dr. Geil gives a brief *résumé* of mediæval China since the building of the wall to the present dynasty—the Manchu. He eulogises the good work done by the Christian missions, and hails the light of a reformation that in the future will make China a world Power of the first rank.

To anyone who knows the intellectual, as well as practical, potentialities of the Chinese, the eventual rise of this Yellow Peril seems far from impossible. Besides the missions of peace that are at work, there are other and rival missions from the armed camps of Europe and Japan urging forward the Chinese, aiding them in rearing a great wall of militarism more formidable than the barrier built by Chi-Hwangti to bar all foreign interference with the internal affairs of "The Central Flowery Land."

In conclusion, this modern view of the Great Wall, with its wealth of illustrations, and the author's discussions over a wide field, should afford instruction and entertainment to the general reader. As a book of travels, further details regarding the route traversed would have been welcome.

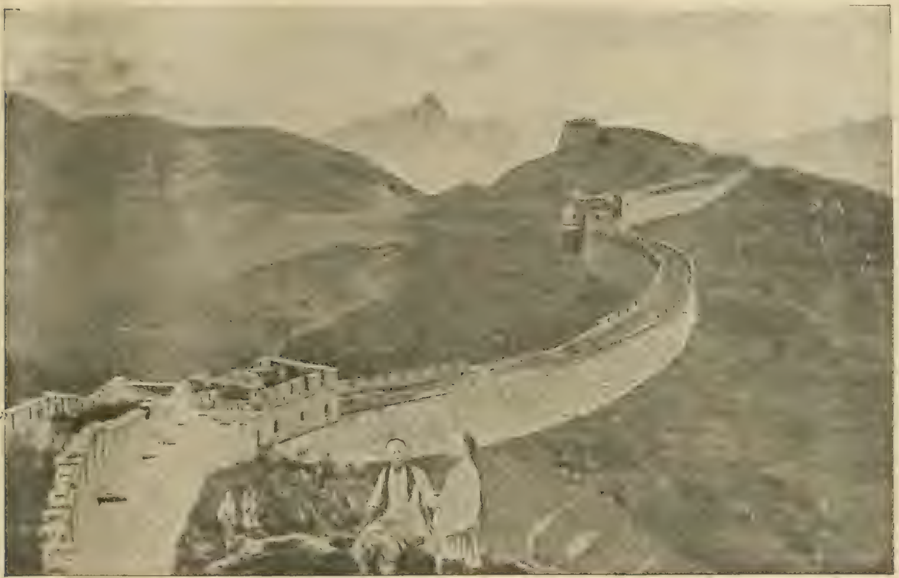

FIG. 2.—Lienhwachih. From "The Great Wall of China."

DR. LUDWIG MOND, F.R.S.

BY the death of Dr. Ludwig Mond this country has lost one of the most eminent of her chemical technologists, and the world is the poorer by the passing away of one who, himself a man of science of no mean attainments, gave liberally of the wealth which his knowledge and skill as a technologist brought him in order to promote the dignity and usefulness of science. Dr. Mond, as he would have been the first to admit, undoubtedly owed much to England, and he gave practical recognition of the extent of his indebtedness by the open-handed generosity with which during his life-time he supported and endowed her scientific institutions. He never forgot that it was through science he had prospered, and he was ever ready to return to the service of science a large measure of the riches she had conferred upon him.

The International Catalogue of Scientific Literature, and the establishment and endowment of the Davy-Faraday Laboratory, are splendid monuments more enduring that brass. With these Dr. Mond's name will for ever be associated. But in reality they constitute only a fraction of the benefits he conferred upon science, for there was hardly a single movement connected with the advancement or spread of physical science which did not find in him a generous and, at times, an enthusiastic and inspiriting supporter. In one other respect, too, his substance was always at the service of science. No appeal from those who enjoyed his confidence, or in whose judgment he had learned to trust, on behalf of the weak brother who had fallen by the wayside, was ever made in vain; and numberless acts of kindness, of sympathy, and of substantial help of which the world knows little or nothing, and of which even the recipients in many cases never knew the source, are recorded to his credit.

But it was not only by his wealth that Dr. Mond served science. In the organisation of science and in her councils he gave of his mental and intellectual powers with the same unstinted liberality that he gave of his material possessions. His knowledge and experience, his remarkable business aptitudes, his skill in the management of men, his faculty for organisation and direction, were freely at the service of every scientific society that had the good fortune to enlist his sympathy, or the wisdom to invite his cooperation.

Ludwig Mond was born in Cassel in 1839, and, after having passed through the Polytechnic of his native place, he went to Marburg to study chemistry under Kolbe. Thence he repaired to Heidelberg to work under Bunsen, and to enjoy his full share of that alternation of study and play—each as strenuous as the other—which characterises the university life of that famous seat of learning. At Heidelberg he took his degree, and, attaching himself to technology, obtained situations in chemical works in Germany. At about this time he was attracted by a problem which had long baffled practical chemists, namely, the recovery of the sulphur employed incidentally in the Leblanc process in the conversion of common salt into soda, and which had passed from the oil of vitriol into the bye-product known as alkali-waste. He devised and patented a process for treating alkali waste, which, although long since superseded by others more economical in working, had a considerably measure of success for a time. He came to England with a view to the introduction of his method into the great alkali works of South Lancashire, Tyneside, and the Clyde district, and it was adopted by a number of manufacturers, notably in Widnes, in Newcastle, and by the Tennants of Glasgow. After a short stay in Holland, where he erected, and for a time managed, a factory to work the Leblanc process, he returned to this country and entered the chemical works of Hutchinson and Earle at Widnes.

Dr. Mond was then twenty-eight years of age. In the previous year he had married his cousin, Miss Frida Loewenthal, and he settled down in the most dismal of all the manufacturing towns in Lancashire with the intention of devoting his talents and energy to the business of manufacturing alkali and the other products commonly associated with it. At this period soda was exclusively made in this country by the Leblanc process, which involves the use of sulphuric acid and the production of large quantities of hydrochloric acid, as well as the formation of the alkali waste already referred to. Other processes had been suggested, and some had actually been brought into successful operation, as, for example, the cryolite process invented by Julius Thomsen, of Copenhagen, and worked so far back as 1857. It was known that common salt might be changed to some extent into bicarbonate of soda by the action of carbonic acid in presence of ammonia. Dyar and Hemming had worked out a method based on this principle, but their efforts to compete with the Leblanc soda resulted in failure, and the firm was ruined. In theory the process was seductively simple, but all attempts to determine the practical conditions needed to ensure complete conversion were unavailing until the method was systematically investigated by two young Belgian chemical engineers, the brothers Solvay, who, in the early 'seventies, devised the modification of the Dyar and Hemming process which has since been known as the ammonia-soda or Solvay process.

Dr. Mond was afforded an opportunity of judging the practicability of the process as thus improved, and so sanguine was he of its commercial possibilities that he determined to embark his little capital in acquiring a licence to work the ammonia-soda process in England. He enlisted the sympathy of his friend Mr. J. T. Brunner (now the Right Hon. Sir John Brunner, Bart., M.P.) with the enterprise, and the result was the formation of the firm of Brunner, Mond and Co., who acquired the Winnington Hall estate, near Northwich, and erected their works over the Cheshire salt deposits. The success of this firm has been phenomenal, and to-day the Winnington works is one of the largest, if not actually the largest, manufactory of the kind in the world. Much of this success was due, in the outset, to the genius and inventive skill of Dr. Mond. In the beginning innumerable difficulties were met with. During the first twelve months, as Sir John Brunner recently said, everything that could explode exploded, and everything that would break broke, until the partners had little left but their credit and their licence from Ernest Solvay. Thanks in large measure to the energy and resourcefulness of Dr. Mond, these troubles were circumvented, and in a surprisingly short space of time the process became a magnificent success. Leblanc soda would have become a thing of the past had it not been for its bye-product, the hydrochloric acid, which alone saved it from extinction.

If the Leblanc process wasted its sulphur, the ammonia-soda process equally wasted its chlorine, and Dr. Mond made repeated attempts to remove this blot on the theoretical cycle of operations upon which the method is based. At one time it seemed as if success had attended his efforts, but the result showed that the economical production of bleaching powder from calcium chloride under existing conditions is a problem which still remains to be solved. Whether the ammonia-soda process has within it the basis of permanent success, time alone can show. As regards the production of ammonia and the means taken for its recovery and preservation, it is difficult to see where fresh economies are possible. In the meantime, new, or at least improved, sources of energy are rapidly becoming available, and every decade shows progress in the methods of transforming this energy into work. Dr. Mond himself devised plans for greatly augmenting its supply, and in the Mond gas there is a relatively cheap source of power which, while it may contribute incidentally to the supply of the all-essential ammonia, may indirectly undermine the stability of the very process with which his name is primarily and more particularly associated. The economical production of alkali from common salt by electrolytic methods in this country is largely a question of the transformation of the potential energy in coal into electrical power, and although theoretically a definite quantity of ammonia is capable of turning an indefinitely large quantity of salt into soda, this can only be effected by the expenditure of energy which itself costs money to produce and apply.

Dr. Mond had a remarkable aptitude for pushing his experimental inquiries into abstract fields of research, and for promptly turning the results to practical account. His discovery, in collaboration with

Langer and Quincke, of an entirely new and altogether unlooked-for group of chemical compounds, now known as the metallic carbonyls, is an admirable illustration of this faculty. The formation of nickel carbonyl—a most interesting substance produced by the direct combination of carbon monoxide with nickel —led to the establishment by him of a new process for the extraction of the metal from its ores which is now in successful operation by the Mond Nickel Company at Swansea.

Dr. Mond was a well-read man of liberal culture and artistic tastes, broad-minded and tolerant, and of a judgment ripened by contact with leading men of all conditions and countries. His merits as a man of science and a technologist were widely recognised. He was an honorary graduate of universities at home and abroad; a Fellow of the Royal Society, and a member of the Accademia dei Lincei. He was president of the Society of Chemical Industry in 1889, and of the chemical section of the British Association in 1896. He was offered the presidency of the Chemical Society a year or so ago, a distinction he was unable to accept owing to the state of his health.

He died on December 11, 1909, in the seventy-first year of his age, and was buried at the St. Pancras Cemetery, East Finchley. T. E. THORPE.

We have received the following short statement of generous assistance afforded by Dr. Mond to the progress of science, in addition to the foundation and endowment of the Davy-Faraday Research Laboratory, of which we hope to give an account in another issue.

Dr. Mond did not restrict his benefactions in science to the direct encouragement of physical and chemical researches. He was an original member of the council of the British Institute of Preventive Medicine (which subsequently developed into the Lister Institute), and gave 2000*l.* towards its foundation in 1893. He also, three years ago, furnished 500*l.* for installing an apparatus for the investigation of caisson disease and of the problems of deep-sea diving. The work in connection with this investigation was carried on by Drs. Haldane and Boycott, and Lieut. Damant, and their results were published in the *Journal of Hygiene*, and in a report to the Admiralty. At Dr. Mond's suggestion, and with the aid of a subsidy from him, a research into the toxicology of nickel carbonyl, a substance he had himself discovered and put to practical use in the manufacture of pure nickel, was carried out by H. W. Armit, who published the results in two papers in the *Journal of Hygiene*.

In the year 1904 Dr. Mond contributed 10,000 lire towards the cost of erecting a laboratory and hostel at Col d'Olen in connection with the International Laboratory of Physiology on Monte Rosa, on the understanding that the Royal Society should have the permanent nomination to two posts in the laboratory.

Shortly after his election into the Royal Society in 1891, he gave practical effect to the deep interest which he felt in scientific bibliography. Indeed, but for his generous and active cooperation it would probably have been impossible for the Royal Society to continue its great undertaking of publishing a catalogue and index of the scientific literature of the last century.

In the second year of his fellowship of the Society Dr. Mond made a donation of 2000*l.* towards the cost of preparing the remaining material of the Catalogue and Subject Index of Scientific Papers, of which the third series was then approaching completion; and at the same time gave a promise of further assistance. This promise was amply fulfilled. Ten years later, in 1902, when the task of dealing with the mass of material published in the last seventeen years of the nineteenth century had to be faced, Dr. Mond offered 6000*l.* in four yearly instalments of 1500*l.* for the purpose of the completion of the catalogue and of the index. Again, in 1906, on the expiry of the four years, he gave a further 6000*l.* in three yearly instalments of 2000*l.* each for the same purpose; and, towards the end of the year 1908, he promised an additional donation of 2000*l.*, with the view of accelerating the publication of the catalogue, and more particularly of the three subject-index volumes for mechanics, physics, and chemistry.

Dr. Mond also took an active part in the inauguration of the International Catalogue of Scientific Literature, now in its seventh year of publication, and his interest in that undertaking continued unabated to the end of his life.

SIR ALFRED JONES, K.C.M.G.

OF all the "slings and arrows of outrageous fortune," I have not often experienced one sharper than the news of the death of Sir Alfred Jones. I am not sure that, broadly looked at, the loss of a battle would not have been more tolerable. For a defeat may be retrieved, but the loss of a commander may be irremediable.

This is to rate his loss pretty high, but not, I think, too much so. For the man was of a quality of which I have not met with the like in the past, nor do I expect to do so in the future. I cannot pretend that I knew him intimately, for he was of that Napoleonic sort which does not invite intimacy. But we were brought together by common interest in public work, where we each strove strenuously by different paths, and where success attended Jones more than could have been hoped for.

Part of the story is told admirably by a sympathetic hand in the *Times*. If I lift the veil a little further, the official indiscretion, if it be such, must be condoned in justice to Jones's memory. An old-fashioned firm, Elder, Dempster and Co. were the shipping agents of Kew in Liverpool. They carried on the trade with the West African colonies which has always been centred there; and in this firm Jones was originally a clerk.

But at the start these colonies were mere trading settlements on the coast which no one at home troubled about so long as they did not trouble. Then came the partition of Africa; the hinterlands were brought under British control, and a new problem immediately arose. If tribal wars are to cease, and an orderly government is to be maintained, a revenue to support it must be raised; and in the last resort this can only be achieved by the promotion of native agriculture and the supply of produce for an export trade.

With these ends in view, Kew succeeded in establishing a number of cheap botanical stations, where plants suitable for cultivation could be grown and propagated, and where the natives could learn cultural methods by inspection. The attempt, for the most part, was rather acquiesced in than encouraged by the colonial officials on the spot, and Jones was perhaps the first to impress spontaneously upon the Colonial Office its importance. He had by that time grasped the future of West Africa, had bought out his old masters, and placed West African trade on an entirely new footing. Incidentally he restored prosperity to the Canaries, and introduced the banana into England. Amongst the principal products of West Africa are various sorts of oil-seeds; for these Liverpool was hardly more than an *entrepôt*, as their principal market was in France. To utilise them at home, Jones started large oil-mills. All this, so far as it goes, only reveals the enterprise and sagacity of a far-seeing man of business; but his subsequent work for the West Indies shows a different side to his character.

The sugar-bounty system had crippled the sugar-industry in the West Indies, and there was much distress amongst the planters and population. In 1896 Mr. Chamberlain sent out a Royal Commission to report on the position, and I willingly assented to the Assistant Director, now Sir Daniel Morris, accompanying it as scientific adviser. I sat one evening under the gallery of the House of Commons to hear Mr. Chamberlain make an eloquent appeal for a subsidy in aid of the distressed colonies. It was passed without demur. But something more than temporary aid was needed, and in 1898 Morris left Kew on his appointment as Imperial Commissioner of Agriculture in the West Indies. On the eve of his departure, happening to be at the Colonial Office, I was told that it was desired to get in touch with Alfred Jones. At that time I had never even seen him, but I invited him by telegraph to meet Morris and the Colonial Office men at dinner. That night the Direct Line was virtually agreed upon. As Jones left he remarked to me that the dinner had only cost him a quarter of a million. Later on he wrote that he was having steamers built in every available yard in the kingdom. At a semi-official gathering this year, the last time I saw him, Jones remarked that the dinner was still not paid for. But throughout his object was not limited to commercial success. He wanted to do for the West Indies what he had done for the Canaries. Morris, by botanical stations and agricultural instructors, sought to turn the negroes into peasant cultivators; Jones to provide an outlet for the produce. But he did much more, and in order to attract tourists he took the defunct hotel industry in Jamaica into his own hands.

Jones was, of course, a man of business, but in no ordinary sense. Commercial success was necessary to him as a justification of his plans, but I think still more as supplying means for extending them. It is no affectation to say that he, of all men, thought imperially. To knit the interests of the home country, and not least of Liverpool, with those of our colonial possessions was the real aim of his life. He offered the Rhodes scholars a free passage from any port at which his ships were available, and one of his latest schemes was to send out parties of undergraduates to make the personal acquaintance of the West Indies. On his last visit to them he took out a large number of distinguished guests. The event was tragic: in the earthquake Sir James Ferguson was killed in the street, and Jones himself was only extricated from the ruins of a falling hotel by little short of a miracle. It may be feared that the strain and shock left effects which were unperceived at the time.

But two other even greater achievements must be mentioned. In 1890–1 I had succeeded in getting the cultivation of cotton experimentally tested in West Africa, and had had samples grown there valued at Manchester. But there the thing ended; it required a more vigorous impulse than mere demonstration. Jones habitually projected his ideas into the future. He saw that cotton-growing in the United States was limited by physical conditions, and could not be extended; that Indian cotton, for reasons too long to explain, was not available; and that the amount which the United States could spare must be a constantly diminishing quantity. He saw that fresh and independent supplies must be found. He virtually started the British Cotton-growing Association, and helped it to raise large funds, amounting to some quarter of a million. Jones possessed the electric power of stimulating more sluggish temperaments. With Morris's aid, cotton-growing was successfully re-established in the West Indies. Jones pushed it for all he was worth in West Africa, and Northern Nigeria promises to be the greatest cotton-growing area in the world.

The importance of this achievement, however, shrinks before that which was perhaps the most remarkable of all. So far as I know, Jones had no scientific training; but he had a fixed belief in the value of scientific knowledge. There are plenty of business men who are ready, so to speak, to pluck the pear when it is ripe, careless who grew it. But Jones looked confidently to scientific method to help on the solution of unsolved problems. If commerce was to be carried on with tropical countries, it must be possible for Europeans to live in them. From his point of view it was not sufficient to treat the local diseases; it was necessary to trace them to causes which could be obviated. He therefore, in perfectly simple faith, founded and endowed the Liverpool School of Tropical Medicine, and sent out one scientific expedition after another to investigate on the spot. Cattle rearing in the West Indies is hampered by diseases which are transmitted by "ticks." Jones sent out Prof. Newstead to study their life-history; he saw that if you could control the tick you could master the disease. But you cannot control the tick until you know everything about it. I could give a striking illustration of a more futile procedure by our own Board of Agriculture.

Jones had, in fact, the true scientific instinct. He knew nothing about science, but he thoroughly believed in the validity of its methods. It is for this reason that he deserves commemoration in these pages. There are probably men like him in America; they are certainly rare in this country; Mond may have been one, but then he was not of English birth.

As I have said, I did not know Jones intimately, and I have therefore been able to write of what he did only as I saw it from outside. He lived a strenuous life, and was a man of few words. The *Times* speaks in terms which I can well believe of his private generosity. I wrote to him on behalf of an orphan boy of promise in the village from which I write. Jones would promise nothing; but the boy got the post he desired in the engine-room of one of his ships.

Jones was a Welshman, and therefore, I suppose, a Celt. Perhaps to this he owed the buoyant optimism and that quality of imagination which is the primary element of success in science as in business. The great enterprises which he started probably possess sufficient momentum to continue; but the resourceful directing spirit is extinguished, and it is a national loss. He was not without honours amongst his own people in Lancashire. In 1901 he was created K.C.M.G. for his colonial services. But the distinction he most deeply prized was his election, without academic standing, as an honorary fellow of Jesus College, Oxford, a recognition which scarcely honoured the electors less than the recipient.

W. T. THISELTON-DYER.

NOTES.

WE regret to announce the death, on December 18, at Weybridge, of Dr. Shelford Bidwell, F.R.S., in his second-second year.

THE council of the Linnean Society has decided to devote the next meeting, on January 20, to a discussion on the origin of vertebrates, in which it is expected that Dr. Gaskell, Dr. Gadow, Mr. Goodrich, Prof. Starling, Prof. MacBride, Dr. Smith Woodward, and Prof. Dendy will take part.

The University of Paris has been authorised, we learn from the *Revue scientifique*, to accept the gift made last June by M. Henry Deutsch. The gift, which amounts to 500,000 francs, and yields an income of 15,000 francs, is to be devoted to the inauguration of an aërotechnical institute for the encouragement of research, having for its object the perfecting of machines for aërial navigation. The institute is to be established at the St. Cyr School, and it is hoped that it will be opened in May next.

The inaugural meeting of the Nature Photographic Society was held at the Institute of Science, Art, and Literature, Leeds, on December 11, Mr. J. J. Ward presiding. The primary object of the society is to form a fellowship among nature photographers in all parts of the world. The president is Mr. Richard Kearton, and the vice-presidents are Messrs. J. J. Ward, F. Martin-Duncan, H. Irving, and O. G. Pike. The secretary is Mr. Carl Edwards, Woodlesford, Leeds, who will be glad to supply particulars to all who are interested in the work of the society.

We learn with regret that Dr. Enrico Hillyer Giglioli, professor of zoology and director of the Royal Zoological Museum in Florence, died on December 16 after a short illness. Dr. Giglioli was commendatore of the Order dei Santi Maurijis e Lazzaro and of the Corona d'Italia, commandeur of the Franz Joseph Order and of the Mérite agricole, officer of the Instruction publique de France and of the Brazilian Order of the Rose. He was born in London on June 13, 1845, and completed his studies in Pisa in the year 1864. The following year he made a voyage of exploration on the Royal ship *Magenta*. In 1869 he was called to the University of Florence, where he was made extraordinary professor in 1871, and ordinary professor three years later. In 1896 he founded the collection of the Italian vertebrates, and later he published his "Avifauna italica," which reached its second edition in the year 1906. On December 20 Prof. Giglioli would have celebrated his fortieth year of teaching; and his death a few days before this proposed celebration has deprived his colleagues, friends, and pupils of the anticipated pleasure of offering him their congratulations upon his work. By the death of Prof. Giglioli one of the leaders of zoology, ornithology, and anthropology in Italy has passed into silence.

Mr. Otto Beit has made a munificent gift of 215,000*l.* for the foundation and endowment of medical research scholarships as a memorial to his brother, the late Mr. Alfred Beit. It may be remembered that some time ago Mr. Alfred Beit provided by his will the sum of 50,000*l.* toward the establishment of an institute of medical sciences. Owing to various circumstances the proposed formation of this institute was abandoned, and the moneys subscribed were returned to the donors or their executors. Mr. Otto Beit has now increased the sum thus received by him as his brother's residuary legatee to 215,000*l.*, which will yield by investment in trustee stocks an annual income of about 7500*l.* In his letter to the Senate of the University of London announcing this generous gift, Mr. Beit asks that the fund shall be named "The Beit Memorial Fellowships for Medical Research," and shall be devoted entirely to the furthering of medical research work in all its branches; or, as the deed of foundation states, "to promote the advancement by means of research of medicine and the allied sciences in their relation to medicine." Each fellowship is to be of the value of 250*l.* a year for three years, and "any man or woman of European descent, graduate of any approved university within the British Empire," will be eligible for election. The fund will be administered by a board of trustees consisting of Viscount Milner, Lord Curzon, Mr. R. B. Haldane, the principal of the University of London (*ex officio*), Mr. Otto Beit, Dr. J. K. Fowler, and Mr. B. F. Hawksley. The advisory board must consist of not fewer than five or more than seven men, all of whom must be members of the medical profession. The first members of the board are Sir T. Clifford Allbutt, K.C.B., F.R.S., Prof. J. Rose Bradford, F.R.S., Dr. J. K. Fowler, Dr. C. J. Martin, F.R.S., Prof. W. Osler, F.R.S., and Prof. E. H. Starling, F.R.S. The first election to the fellowships will take place on or before March 1, 1910, and on or about January 1 of each subsequent year. Except in special cases, the fellows may undertake research only at recognised places in London, so that the work to be promoted by the benefaction will be mainly carried out in institutions connected with the University of London.

When Dr. F. A. Cook returned from north polar regions four months ago and announced that he reached the North Pole on April 21, 1908, we expressed the hope that the observations of position and narrative of the journey would be published at an early date, so that the value of the claim could be decided definitely. In the absence of documentary evidence of this kind, the explorer's statements had to be accepted provisionally, but judgment upon them was reserved. At last the material upon which the claim to have reached the North Pole is based has been submitted to a committee of Copenhagen University appointed to investigate the records of Dr. Cook's journey. The conclusion arrived at by the committee is that the documents are altogether insufficient to prove the attainment of the highest northern latitude. A Reuter message from Copenhagen on December 21 states that the papers submitted to the committee for investigation were:—(1) A type-written report by Mr. Lonsdale on Dr. Cook's Arctic voyage, consisting of sixty-one folios. (2) A type-written copy of sixteen folios, made by Mr. Lonsdale, comprising the note-books brought back by Dr. Cook from his journey, and covering the period from March 18 to June 13, 1908, stated to have been written on the way from Svartevaag to the Pole and back until a place west of Heibergsland was reached. The committee points out, as a result of its investigations, that the afore-mentioned report of the journey is essentially identical with that published some time ago in the *New York Herald*, and that the copy of the note-books did not contain astronomical records, but only results. In fact, the committee remarks that there are no elucidatory statements which might have rendered it probable that astronomical observations were really taken. Neither is the practical side, namely, the sledge journey, illuminated by details in such a way as to enable the committee to form an opinion. The committee therefore considers that from the material submitted no proof can be adduced that Dr. Cook reached the North Pole. The council of the University accordingly declares as a result of the committee's report that the documents submitted to Copenhagen University contain no observations or explanations to prove that Dr. Cook on his last polar journey reached the North Pole.

The December number of the *Entomologist's Monthly Magazine* contains announcements of several additions to the British insect-fauna, among the most interesting of which is the brachelytrous beetle *Proteinus crenulatus*, obtained by Dr. D. Sharp at Netley Bridge in 1906, and again in 1907. In Spry and Shuckard's "British Coleoptera" three of the five European species are recorded as British; Dr. Sharp has been enabled to include the whole five in our fauna.

According to the report for 1908–9, the committee of the Leicester Museum and Art Gallery has sanctioned large and important additions to the buildings under its charge. The additions include a new entrance-hall, an extension of the main building, with the conversion of the greater portion of the ground-floor into a central hall, the replacement of the first floor by a gallery, and the construction of a new staircase. It is also proposed to erect and equip suitable work-rooms, to build a new wing on the west side of the present structure, and to devote the room now containing invertebrates to art purposes.

Circular No. 113 of the Entomological Bureau of the U.S. Department of Agriculture is devoted to the chinch-bug (*Blissus leucopterus*) and its ravages. No other insect indigenous to the western hemisphere has spread its devastating hordes over a wider tract than has this species, and were it not for the destruction of the larvæ by heavy rains, and, in a less degree, the diminution in its numbers by the attacks during the rainy season of a parasitic fungus, continuous corn-growing in many parts of the United States would have long since become impracticable owing to this insect. The present circular, after giving a detailed and illustrated account of the insect in its various developmental phases, summarises the history of its periods of greatest increase and its gradual spread, concluding with a description of the various methods which have been proposed to check and control its increase.

Nos. 1704 and 1705 of the Proceedings of the U.S. National Museum are devoted to molluscs, the first of these containing an account, by Mr. W. H. Dall, of a collection of marine shells from Peru, with a summary of the littoral marine mollusca of the Peruvian zoological province, while in the second Mr. P. Bartsch describes four new species of Philippine land-shells. In connection with the Peruvian province, Mr. Dall directs special attention to the unusual prevalence of black, blackish, or lurid colouring among the molluscs, this being particularly noticeable in the phytophagous group. It has been attempted to explain this phenomenon, which has long been known, by the suggestion that it is correlated with the presence of the vast beds of kelp so characteristic of the Peruvian coast; but it is pointed out that similar dark beds of kelp on the Californian coast give shelter to some of the most brilliant trochids and other molluscs, while green sea-weeds occur abundantly on the rocks below low-water mark on the coast of Peru. Evidently, therefore, some other explanation is required.

In a paper published in a recent number of the *Journal of Physiology* (vol. xxxix.) Dr. H. M. Vernon suggests a hypothesis of tissue respiration founded on ferment action. Dakin has shown that, in accordance with the well-known Fenton reaction, hydrogen peroxide, in the presence of ferrous sulphate as activator, is able to oxidise various amino-acids and fatty acids completely to carbon dioxide and water. Aldehydes are formed as intermediate products. Similarly in living tissues it is thought that intramolecular oxygen is taken up in the form of an organic peroxide and is transferred by the help of an intracellular peroxydase ferment to oxidisable substances. The presence of aldehyde groupings in animal tissues is strongly supported by the fact that poisons such as hydrocyanic acid, sodium fluoride and acid sodium sulphite, which are known to be capable of forming loose combinations with aldehydes, temporarily deprive the tissues of their respiratory power without necessarily doing them any permanent injury. Other poisons, such as formic aldehyde, temporarily prevent the tissues from forming carbon dioxide, though not from absorbing oxygen. It is suggested that they act by destroying peroxydase, so that the peroxide of the tissues, in the absence of activator, can only effect incomplete oxidations.

The study of nuclear changes and qualities in the mutants and hybrids of Œnothera offers a promising field of investigation. Mr. R. R. Gates, who has already contributed some papers on the subject, furnishes in the *Botanical Gazette* (September) a further account of the chromosomes in the hybrid *O. lata* × *O. gigas*. There are normally twenty-one (rarely twenty) chromosomes in the somatic cells as compared with fourteen in *O. lata* and twenty-eight in *O. gigas*. At the reduction stage half the germ-cells receive ten and half receive eleven chromosomes, but there are occasional irregularities, as when the germ-cells receive nine and twelve respectively. The author argues that this segregation is not a pairing and separation of homologous chromosomes of maternal and paternal origin, but merely a division into numerically equal groups.

Algology has formed the subject of several papers by Mr. F. S. Collins which have been published in *Rhodora* and other American publications. In his latest contribution, that appears as vol. ii., No. 3, of Tuft's College Studies, he undertakes the ambitious task of compiling a flora of the green algæ of North America. The bulk of the species are marine algæ collected on the shores of the United States, but the author recognises that Greenland, Canada, Mexico, and the West India islands fall within his province, and includes records of fresh-water algæ so far as they exist. The work contains short diagnoses of all the species, keys to the species, genera, and families, and a figure for each genus, thus providing a serviceable handbook for American algologists, and one that is likely to attract workers to the subject. The author distinguishes two main groups, the Heterokontæ, so-called because the motile cells have cilia of unequal length, and the Chlorophyceæ. The family of Desmidiaceæ is omitted, because it is too extensive.

We have received from Prof. Hergesell a preliminary summary account of the participation of various countries in the international kite and balloon ascents during the quarter ended June last. In addition to many places in Europe and the United States, ascents were made at Samoa and by the Greenland Scientific Expedition. The greatest altitude reached by registering balloons was 27,100 metres, at Munich on May 7. Heights of 20,000 metres and above were attained by the ascents from Glossop (Manchester), Hamburg, Strassburg, Uccle (Brussels), and Zürich. The meteorological results will be published elsewhere.

In addition to the elaborate monthly and seasonal meteorological charts of the Atlantic and Pacific Oceans issued by the U.S. Weather Bureau, to which we have already directed attention, we have received a copy of a handy "Marine Calendar," showing for each month the average weather conditions of the North and South Pacific, the storm and hurricane signal code, and the moon's changes for 120th meridian time (besides the usual almanac). Following the calendar are tables for the conversion of time of one country to that of another to the nearest second. The calendar will be found very convenient for the purposes intended, and will further popularise the useful marine work of the Weather Bureau.

An appendix to the report of the International Conference on Electrical Units and Standards of 1908 has just been issued. It will be remembered that the specifications of the ohm, ampere, and normal cell in the original report were expressed in general terms so as to admit of modifications in details at the various national standardising laboratories. The appendix now issued contains details of the methods adopted at the National Bureau of Standards of America, at the Central Electrical Laboratory of Paris, at the Reichsanstalt at Berlin, and at the National Physical Laboratory at Teddington. References to the literature of the subject are also given, so that this appendix will prove of great use in electrical laboratories.

THE *Naturwissenschaftliche Wochenschrift*, the organ of the German Society for Popular Science of Berlin, devotes almost the whole of its issue of December 4 to the first of a series of three articles on the experimental foundations of the atomic theory, by Mr. Werner Mecklenburg. After a short historical introduction the author deals with the evidence for the existence of discrete particles in optically clear colloidal solutions, and then goes on to the kinetic theory of gases as one of the means of determining the size of the actual molecule of matter. Under this head simple proofs of Boyle's law, of the relation between mean free path and viscosity, of Van der Waals's equation, and of Loschmidt's method of calculating the radius of a molecule are given. As the method of treatment of the subject is not unlike that adopted in Meyer's kinetic theory of gases, readers of the above weekly must be interested in science to a greater extent than the public generally gets credit for being.

MESSRS. BURROUGHS, WELLCOME AND CO., of Snow Hill Buildings, E.C., have issued their exposure record and diary for 1910. This pocket-book is so well known among photographers that the chief object of this note is to inform them that the 1910 issue is now ready. It is important to point out that three editions are issued and bound in different tints, according as they are especially arranged for the northern or southern hemisphere or for the United States of America. The pocket-book itself is a mine of practical information set up, so to speak, in tabloid form, and the concentrated essence of the contents, together with the pages for entering exposure records and for a whole diary, is all enclosed in a very neatly got-up covering which will stand constant wear and tear. It must not be forgotten that a very important feature is the mechanical exposure calculator, practically the simplest efficient instrument, which is fastened inside the back cover. One turn of one scale tells the correct exposure for any subject, at any time of the day or year, in any part of the world. The writer of this note has used one of these books for several years, and finds, to his regret, that to be without his copy means a great uncertainty in giving correct exposures. Issued at a price of one shilling, it is an extremely good investment.

A NEW apparatus has recently been installed in the mechanical engineering department of the Northampton Institute for testing aëroplane models, and is described in an article, by Messrs. C. E. Larard and R. O. Boswall, in *Engineering* for December 10. The apparatus consists essentially of a carriage supported on four wheels running on a long straight track, and carrying the model aëroplane. The carriage is drawn along with increasing velocity by means of a horizontal cord, which is attached to the carriage at one end and to a large drum at the other end. The drum is rotated by falling weights, and the velocity of the carriage at any instant is obtained from a record traced on a moving strip of paper by a vibrator making five complete vibrations per second. When a sufficient velocity has been attained the model lifts, *i.e.* flight begins, and the instant at which this occurs is marked on the strip of paper electrically. The velocity at which flight begins can thus be determined easily. The authors prefer this form of apparatus to the whirling-table method, and hope to make a series of tests on planes of varying shapes and dimensions. Experiments are now being made to determine the velocities at different angles, and also to show the manner in which the centre of pressure alters as the angle of the plane is varied. It is also proposed to instal a considerably larger apparatus than the existing one, which has a track 60 feet long at present.

THE twenty-sixth annual issue of the "Year-book of the Scientific and Learned Societies of Great Britain and Ireland" has been published by Messrs. Charles Griffin and Co., Ltd. The book has been compiled from official sources, and is intended to be a record of the work done in science, literature, and art during the session 1908–9 by numerous societies and Government institutions. In some cases the lists of papers read before societies are a little belated. For instance, it should have been possible in December, 1909, to publish the titles of papers read at the Winnipeg meeting of the British Association last summer in the place of those read in Dublin in 1908. Exhaustive though the list of societies is, it is not yet complete. Certain local geographical societies are dealt with, but the Geographical Association, with its numerous branches, receives no mention—an omission we have pointed out on a previous occasion.

OUR ASTRONOMICAL COLUMN.

DANIEL'S COMET, 1909*e*.—Dr. Ebell's ephemeris for Daniel's comet, 1909*e*, is extended to January 2, 1910, in No. 4376 of the *Astronomische Nachrichten* (p. 127, December 14), and the following is an extract therefrom:—

Ephemeris 12h. M.T. Berlin.

1909	α (true) h. m.	δ (true) ° ′	log r	log Δ	Brightness
Dec. 21	6 19·0	+45 34·7	0·2009	0·8022	0·92
,, 25	6 19·2	+48 15·8	0·2032	0·8128	0·87
,, 29	6 19·4	+50 40·7	0·2059	0·8255	0·81
1910					
Jan. 2	6 19·6	+52 47·8	0·2092	0·8404	0·74

The elements given by Dr. Ebell show a likeness to those calculated by Dr. Becker for comet 1867 I. (Stephan), which are given for comparison; the "period" given in the latter is 40·1±2·0 years. A number of observations are recorded in the same journal. On December 8 the comet was easily seen in the 8-cm. (3·2 inches) finder at the Uccle Observatory, and appeared to be of about magnitude 9·5; a nucleus of the twelfth magnitude and about 12″ in diameter was seen to be surrounded by a coma which was 3′ in diameter. Observers at Algiers and Arcetri on December 9 estimated the magnitude at 10·5 and 11·5 respectively.

HALLEY'S COMET.—Visual observations of Halley's comet with small instruments are now becoming common, and a number are recorded in No. 4376 of the *Astronomische Nachrichten*. Prof. Nijland reports that the comet was certainly visible in a 73-mm. finder on December 5, its magnitude being estimated as 11·0. Herr v. Buttlar, using a 3½-inch telescope on December 4, saw the comet as a nebulous mass of about 45″ diameter, having a magnitude of about 11·5.

SUBJECTIVE PHENOMENA ON MARS.—In No. 4358 of the *Astronomische Nachrichten* M. Antoniadi suggested, because it is not shown on photographs, that the dark band which surrounds the disappearing polar cap on Mars is probably a subjective phenomenon. In a later number (4363) of the same journal M. Jonckheere contested the subjectivity of a band which was irregular in form and might be obliterated from the photographs by the photographic "spreading" of the image of the brilliant polar cap.

To these suggestions M. Antoniadi replies, in No. 4376,

(1) that the irregularities are not in the band itself, but are due to a number of real, grey spots which are left isolated by the retreat of the disappearing cap; (2) that the distance of the dark band from the edge of the cap is too great to be covered by the "spreading" of the image of the latter. Further, he continues, if the phenomenon of the dark band is real, it should obey the ordinary laws of perspective, and should appear about two and a quarter times as broad at the extremities of the major axis of the projected cap as it does at the ends of the minor axis; but the majority of drawings show the band to be the same width all round, and M. Antoniadi therefore contends that it is a subjective effect produced by contrast.

TEMPERATURE CLASSIFICATION OF STARS.—In No. 4375 of the *Astronomische Nachrichten* Drs. Wilsing and Scheiner publish a list of 109 bright stars of which they have determined the effective temperatures by spectral photometric observations. The temperatures determined range from 2800° (absolute) for χ Serpentis, to 12,800° for λ Orionis, and, in a summary, the range from Vogel's type Ia1 to type III. is given as 9600°–3200°.

Dr. Nordmann, also, has recently published several notes, in the *Comptes rendus*, giving the results obtained by his method of photometric comparisons of various definite regions of the spectra. In No. 4 he gave a list of fifteen temperatures ranging from 2870° to >60,000° (absolute), and compared the order in which the stars were thus arranged with the order given, for the same stars, in Sir Norman Lockyer's temperature classification. The latter, of course, does not deal with actual temperatures, but in general the two arrangements were found to agree fairly well; Dr. Nordmann's value for the solar temperature also agrees well with the values determined by previous observers. In a later note confirmation of the temperature given for Algol was obtained by an independent method, whilst in the most recent publication (*Comptes rendus*, No. 23, December 26) Dr. Nordmann gives amended values of the temperatures primarily published. The only important alterations are found towards the upper temperature limit, and do not involve any rearrangement of the sequence; the highest temperature (for λ Tauri) is now given as >40,000°.

A NEW VARIABLE STAR, OR A NOVA.—In No. 4375 of the *Astronomische Nachrichten* Prof. Ceraski announces that on a plate taken on March 23, at 10h. 6m. to 12h. 6m. (M.T. Moscow), Madame Ceraski discovered an image of a tenth-magnitude object which is absent from twenty-four earlier plates, showing 12·5 magnitude stars, of the same region. The approximate position of this object is 8h. 29m. 26s., +53° 50′ (1900), and the shape of the image shows it to be a star; the suggested explanations that it might be a planet or an end-on meteor are thought to be improbable, and Prof. Ceraski suggests that all observers having plates of this region should examine them for traces of what may be either a nova or a new variable star.

THE "COMPANION TO THE OBSERVATORY."—Edited by Messrs. T. Lewis and H. P. Hollis, and published, at 1s. 6d., by Messrs. Taylor and Francis, this annual is the most generally useful, to the practical, general astronomer, of all the British annual publications. The issue for 1910 differs but little in form from its immediate predecessors, the usual contributions having been obtained from Mr. Denning, Dr. Maw, Mr. Crommelin, and M. Baillaud.

THE RELATION OF SCIENCE TO HUMAN LIFE.[1]

IN casting about for a suitable introduction for my address this afternoon, I came across some words written by a great Englishman, which with your permission I will read to you.

"Remember the wise; for they have laboured, and you are entering into their labours. Every lesson which you learnt in school, all knowledge which raises you above the savage and the profligate—who is but a savage dressed in civilised garments—has been made possible to you by the wise. Every doctrine of theology, every maxim of morals, every rule of grammar, every process of mathematics, every law of physical science, every fact of history or of geography, which you are taught, is a voice from beyond the tomb. Either the knowledge itself, or other knowledge which led to it, is an heirloom to you from men whose bodies are now mouldering in the dust, but whose spirits live for ever and whose works follow them, going on, generation after generation, upon the path which they trod while they were upon earth, the path of usefulness, as lights to the steps of youth and ignorance.

"They are the salt of the earth, which keeps the world of man from decaying back into barbarism. They are the children of light. They are the aristocracy of God, into which not many noble, not many rich, not many mighty, are called. Most of them were poor; many all but unknown in their own time; many died and saw no fruit of their labours; some were persecuted, some were slain, as heretics, innovators and corruptors of youth. Of some the very names are forgotten. But though their names be dead, their works live, and grow and spread over ever fresh generations of youth, showing them fresh steps towards that temple of wisdom which is the knowledge of things as they are; the knowledge of those eternal laws by which God governs the heavens and the earth, things temporal and eternal, physical and spiritual, seen and unseen, from the rise and fall of mighty nations to the growth and death of moss on yonder moors."

So spake Charles Kingsley, and his words I make use of as an introduction which strikes the key-note of what I have to say to you to-day.

The subject which I have chosen for my address—the relation of pure science, and especially of biological science, to human life, and inferentially the relation which ought to exist between pure and applied science in a college of science—is naturally of great interest to us in the Imperial College, which is a college of science and technology, and the purposes of which are, in the words of the charter, "to give the highest specialised instruction and to provide the fullest equipment for the most advanced training and research in various branches of science, especially in relation to industry." Particularly do I desire to set forth as clearly as I can the justification for including in a college which deals, not only with science, but with science in relation to industry, those branches of science which deal with organisms.

As industry forms the principal occupation of human life, and as the phenomena of organisms constitute the science of life, it may seem absurd to set out solemnly to justify the inclusion of the biological sciences in a college which deals with science especially in its relation to human life. Nevertheless, having regard to the fact that I have heard some doubt expressed as to whether the cult of the biological sciences properly falls within the scope of the Imperial College, it may not be out of place to bear the matter in mind on this, the second, occasion of the prize-giving of our new college.

What is the meaning of the word *science?* As in the case of so many words, its meaning has become confused by its partial application, *i.e.* by its application to a part only of its contents, and this has often led to a misapprehension of the relation of science and of the scientific man to life. Science simply means knowledge, and to speak of scientific knowledge, as opposed to ordinary knowledge, is to use a redundant phrase, always supposing that we are using the word knowledge in its strict sense. Huxley defined science as organised common sense, by which, I take it, he meant knowledge of things as they are—knowledge the reality of which can at any time be checked by observation and experiment; for common sense, if it is anything, is the faculty by which we are made aware of reality. Science is sometimes spoken of as exact knowledge, but I am bound to say that I do not like the phrase exact knowledge; it seems to imply an insult to the word knowledge. Its use reminds me of a friend of mine who, when he was offered one morning at breakfast a fresh egg, mildly asked, "In preference to what other kind of egg?" It recalls those regrettable phrases one so often hears, I *honestly* believe, or I *honestly* think; one wonders how the people who make use of them usually believe and think.

It must, I think, be admitted that science simply means knowledge, and that there is nothing peculiar about the knowledge of scientific men by which it differs from other knowledge.

---

[1] Address delivered at the Imperial College of Science and Technology on December 16 by Prof. A. Sedgwick, F.R.S.

Scientific men are not a class apart and distinct from ordinary mortals. We are all scientific men in our various degrees. If this is so, how comes it that the distinction is so often made between scientific men and non-scientific men, between scientific knowledge and non-scientific knowledge? The truth appears to lie here: though it is true that all men possess knowledge, *i.e.* science, yet there are some men who make it their main business to concern themselves with some kind of knowledge, and especially with its increase, and to these men the term scientific has been technically applied. Now the distinctive feature of these men, in virtue of which the term scientific is applied to them, is that they not only possess knowledge, but that they make it their business to add to knowledge, and it is this part of their business, if any, which justifies their being placed in a class apart from other possessors of knowledge.

The men who make it their main business to add to knowledge may be divided into two classes, according to the motive which spurs them on. (1) There are those whose immediate object is to ameliorate the conditions of human life and to add to its pleasures; their motive is utility, and their immediate goal is within sight. Such are the great host of inventors, the pioneers in agriculture, in hygiene, preventive medicine, in social reform and in sound legislation which leads to social reform, and many other subjects. (2) There are those who pursue knowledge for its own sake without reference to its practical application. They are urged on by the desire to know, by what has been called a divine curiosity. These men are the real pioneers of knowledge. It is their work which prepares the way for the practical man who watches and follows them. Without their apparently useless investigations, progress beyond the limits of the immediately useful would be impossible. We should have had no applied electricity, no spectrum analysis, no aseptic surgery, no preventive medicine, no anæsthetics, no navigation of the pathless ocean. Sometimes the results of the seeker after knowledge for its own sake are so unique and astounding that the whole of mankind stands spellbound before them, and renders them the same homage that the child does the tale of wonderful adventure; such is the case with the work on radium and radio-activity, which is at present fixing the attention of the whole civilised world. Sometimes the work is of a humbler kind, dealing apparently with trivial objects, and appealing in no way to the imagination or sense of the wonderful; such was the work which led to and formed the basis of that great generalisation which has transformed man's outlook on nature—the theory of organic evolution; such was the work which produced aseptic surgery and the great doctrines of immunity and phagocytosis which have had such tremendous results in diminishing human pain. The temper of such men is a curious one; no material reward can be theirs, and, as a rule, but little fame. Yet mankind owes them a debt which can never be repaid. It is to these men that the word scientific has been specially applied, and with this justification—they have no other profession save that of pursuing knowledge for its own sake, or, if they have a profession, it is that of the teacher, which, indeed, they can hardly avoid. Ought such men, working with such objects, to find a place in the Imperial College?

It is a curious thing, but it has only comparatively recently been realised, that a sound and exact knowledge of phenomena was necessary for man. The realisation of this fact, in the modern world at any rate, occurred at the end of the Middle Ages; it was one of the intellectual products of the Renaissance, and in this country Francis Bacon was its first exponent. In his "Advancement of Learning" he explained the methods by which the increase of knowledge was possible, and advocated the promotion of knowledge to a new and influential position in the organisation of human society. In Italy the same idea was taught by the great philosopher Giordano Bruno, who held that the whole universe was a vast mechanism of which man, and the earth on which man dwells, was a portion, and that the working of this mechanism, though not the full comprehension of it, was open to the investigation of man. For promulgating this impious view both he and his book were burnt at Rome in 1600. You will find the same idea cropping up continually in the written records of that time; Copernicus gave it practical recognition when he demonstrated the real relation of the earth to the sun, and it was thoroughly grasped by our own Shakespeare, who gave it expression in the dialogue between Perdita and Polixines in the *Winter's Tale*:—

Perdita. The fairest flowers o' the season
Are our carnations and streaked gillyvors,
Which some call Nature's bastards: of that kind
Our rustic garden's barren; and I care not
To get slips of them.
Polixines. Wherefore, gentle maiden, do you neglect them?
Perdita. For I have heard it said
There is an art which, in their piedness, shares
With great creating nature.
Polixines. Say there be;
Yet nature is made better by no mean,
But nature makes that mean: so, o'er that art
Which you say adds to nature, is an art
That nature makes. You see, sweet maid, we marry
A gentle scion to the wildest stock and make conceive a bark of baser kind
By bud of nobler race: this is an art
Which does mend nature,—change it rather; but
The art itself is nature.

It is not difficult for us, though it may be difficult to our descendants, to understand how hard it was for man to attune himself to this new, this mighty conception, and the intellectual history of the last three hundred years is a record of the struggles to make it prevail.

Trained through long ages to believe that the heavens were the abode of the gods, who constantly interfered in the daily affairs of life and in the smallest operation of nature, it seemed to men impious to maintain that the earth was in the heavens, and to peer into the mysteries which surrounded them, and the endeavour to do so has been stoutly resisted; but the conflict, in so far as it has been a conflict with prejudice, is now over. It vanished in the triumph of the modern views on the origin of man which will be for ever associated with the names of Lamarck, Spencer, and Darwin.

The triumph of these views does not mean that they are correct or that we know anything more about the great mystery of life than we did before. He would be a bold and a prejudiced man who made that assertion. What it means is this, that man is grown up, that he has cast off the intellectual tutelage under which he has hitherto existed, that he has attained complete intellectual freedom, and that all things in heaven and earth are legitimate subjects of investigation. But it means even more than this; it means that the conviction is rapidly growing upon him that the only way in which he can hope to improve his condition is by understanding the laws, physical as well as spiritual, under which he exists, and this he is determined to try to do by the only method open to him—that of minute and arduous research.

And is it, I ask, an unworthy ambition for man to set before himself to understand those eternal laws upon which his happiness, his prosperity, his very existence depend? Is he to be blamed and anathematised for endeavouring to fulfil the divine injunction, *Fear God and keep His Commandments, for that is the whole duty of man?* Before he can keep them, surely he must first ascertain what they are!

We hear a great deal nowadays about the humanities and the humane studies—the study of "ancient elegance and historic wisdom"—and I should be the last to minimise in any degree the value and intense interest which is attached to the study of the writings and utterances of the mighty dead. They will always retain undimmed their attraction and inspiration for man, and man will always think with gratitude and affection of their authors; but it is possible to overdo a thing, and this talk of the humanities and humane studies has been overdone. After all, a live dog is better than a dead lion—but in this case we are dealing with a living lion.

It is ridiculous to say nowadays that the study of the humanities consists solely of the study of the writings and philosophy of the ancients; to take that view is to take the view of the schoolmen, the death-blow to which was given by Bacon and Bruno.

We have got beyond that; we claim that the true study of the humanities is a far wider thing—it is the study of the stupendous mechanism of the universe of which man forms a part, and the understanding of which is necessary for his happiness. That is the true humanity of which the other forms only a small portion. The time is coming when the principal preoccupation of man shall be the gradual disclosure of this mechanism and his principal delight the contemplation of its beauty. For remember what Plato himself said: the whole of nature, so far as it really exists, is a revelation of God.

In spite of the work and writings of such men as Bacon and Bruno in the end of the sixteenth century, the progress of science was at first but slow and the workers few. We have, of course, the immortal achievements of Newton and Harvey, and the foundation of the Royal Society, and the tremendous outburst of scholarship as typified in this country by Bentley and his co-workers; but the eighteenth century was, on the whole, characterised by intellectual quiescence both in scientific output and in literary creation. The quiescence was apparent rather than real. To borrow a metaphor from the garden, though there was little growth above ground, active root formation was going on. Linnæus (1707–78) was at work in Sweden creating the framework which rendered future work in botany and zoology possible; Buffon in France was cautiously feeling his way towards a theory of organic evolution; Henry Cavendish (1731–1810), Joseph Priestley (1733–1804), and Antoine Lavoisier (1743–94) were laying the foundations of modern chemistry; Albrecht von Haller (1707–77), Kaspar Friederick Wolff (1733–94), and John Hunter (1728–93), those of anatomy and physiology. The spade-work of these men, together with the improvement of the microscope, was necessary for the great outburst of scientific investigation which characterised the nineteenth century. Ushered in by the work of Cuvier (1769–1832), Lamarck (1744–1829), St. Hilaire (1772–1844), in biology, Thomas Young (1773–1829), Laplace (1749–1827), Volta (1745–1827), Carnot (1758–1823), in physics, it was adorned in its middle and latter period by the names of Davy, Faraday, Dalton, Arago, Richard Owen, Darwin, Lyell, Joh. Müller, Agassiz, Helmholtz, Stokes, Kelvin, and Pasteur.

The advance of knowledge is yearly becoming more rapid; if its steps were slow and hesitating in the seventeenth and eighteenth centuries, and if it quickened to a rapid walk in the nineteenth, we now hear the sound of a trot, which at the end of the century will be a gallop, and as the centuries succeed one another its pace will become even faster. Where will it lead us, and what will be the upshot for man?

But it is no part of my purpose to-day to give you an historical summary of scientific progress. The point I wish to illustrate is the vast increase in the scientific army and in the results achieved by them.

My thesis is that pure research into the sequence of natural phenomena is in itself of the greatest importance to the progress and welfare of humanity, and that a great statesman can have no higher aim than to solve the problem of how it may best be fostered. To what extent can such a thesis be justified by experience?

I might begin by examining the origin and progress of our knowledge of what is called current electricity, to which modern life, from a material point of view, owes so much. In illustration of what we owe to workers in electrical science I need only mention land telegraphy, ocean telegraphy, wireless telegraphy, telephones, electric light, electric traction, and our knowledge of radio-activity. The history of this science forms, perhaps, the best example of the importance to man of pure, apparently useless, scientific research, for at every stage of it, from Galvani's original observation through the discoveries of the Swede Oersted and of the Frenchman Ampère to those of our own Faraday and to the theoretical adumbrations of Clerk Maxwell and to the researches of Crookes on the passage of electricity through vacuum tubes, we meet with the investigation of phenomena which were apparently perfectly useless, and which to most practical men must at the time they were made have appeared as little more than scientific toys provided by nature for the harmless amusement of the queer people who meet in the rooms of the Royal Society and suchlike places where unpractical oddities resort. And yet I ask you to reflect upon the astounding results which have arisen from Galvani's observations made to discover the cause of the twitching of the frog's legs, and of Faraday's discovery of induction, and to indulge your imaginations in an endeavour to predict what may issue for man from Crookes's investigations of the glow without heat of the vacuum tubes.

But I have neither the knowledge nor the time to dwell upon the physical side of science. As in private duty bound, I must devote the short time at my disposal to examples culled from the biological sciences.

The great Frenchman Pasteur, in making a thorough examination of the process by which alcohol was obtained from sugar, discovered the part played by the organism known as yeast, and established the idea of organised ferment bodies. He extended his observations to other micro-organisms, and, in conjunction with his co-workers, among whom must be included those who were looking into the question of the spontaneous generation of living matter, definitely gave us the idea that putrefaction was caused by micro-organisms acting upon organic matter, that these micro-organisms are capable of resisting drought, and when dried float freely in the air and are distributed everywhere. When they fall upon a suitable material their vital activity is resumed, and they increase with incredible rapidity and set up putrefaction. It was reserved for our distinguished countryman Lister, then a surgeon in Edinburgh, to recognise the importance of these discoveries for surgery. Knowing of the researches of Pasteur and his fellow-workers, he conceived the idea that suppuration was due to putrefaction in the organic matter of the wounds caused by micro-organisms. Acting on this, he introduced his method of antiseptic surgery, by which his name has been rendered immortal. I think we may say that no single application of the results of pure research has done more to preserve human life and to diminish human suffering than this linking up by Lister of the putrefaction of suppuration with the work of his predecessors on the effects of the actions of micro-organisms upon organic matter. It is well to notice, in passing, that this discovery of Lord Lister's is a good illustration of the difficulty which the human mind has of conceiving even the simplest new idea. To us, now, how simple seems the step which Lister made; yet there were thousands of surgeons in the world who failed to make it, though they were continually dealing with suppurating wounds and wondering why they suppurated, and when it was made it was stoutly discredited by many quite able men.

I must now turn to another subject which is closely connected with the preceding, and well illustrates my thesis that pure scientific research, without reference to practical utility, is of the highest importance to mankind.

It will doubtless have occurred to many of you to ask the question, How is it, if the air contains floating in it the dried spores of multitudinous micro-organisms which only need a suitable medium for their development and increase, how is it that they do not obtain a lodgment in the healthy animal body, which one would think offers all the conditions necessary to their growth? It can easily be shown that the air we breathe, the water we drink, the food we eat, everything that we touch, swarms with these microscopic creatures; that they enter our lungs, that they germinate in our skin, that they occur in countless numbers in our alimentary canals, in short, that they are found everywhere on our body surfaces. How is it that they do not increase and turn our organs into a seething mass of putrefying corruption? One would expect that even if the skin and the membrane bounding the internal organs to which they obtain entrance incurred the slightest lesion, even a pin-prick, that they would have been able to enter. We know that after death they at once obtain complete dominion, and we therefore infer that in life there must be some protective mechanism in the body capable of dealing with them.

The discovery that there is such a mechanism was made in the early 'eighties by the distinguished Russian zoologist Elias Metschnikoff, though the need of its existence was not recognised by biologists in general until later. The result of this was that his remarkable discoveries were at first pooh-poohed and discredited by many, but ultimately they gained acceptance, and their further development in his own hand and that of others has wrought a revolution in the art of preventive medicine.

The mechanism consists of the small amœboid cells found in the blood, lymph, and body fluids generally, and called leucocytes, or white blood corpuscles. Though long known to exist, very little had been ascertained as to their function until Metschnikoff, working at such remote subjects as the embryology of sponges, the structure and digestion of polyps, the blood of water-fleas, realised that these small amœba-like cells, which exist in all organisms, actually swallow, digest, and so destroy small foreign bodies which have invaded the organisms. He called them the phagocytes, and all his subsequent work has been directed to the elucidation of their mode of action.

It is to Metschnikoff's work, prompted solely by the scientific spirit, that we owe our knowledge of phagocytosis and the great theory of immunity which has proceeded from it. It is impossible at the present moment to estimate fully the value to man of Metschnikoff's discoveries. Suffice it to say that they have already led to important practical results, and have revolutionised treatment.

I must now turn for a moment to another subject of the greatest importance to mankind, and one which has been brought into notice by the researches, perfectly useless so far as our material welfare is concerned, which were undertaken with the view of elucidating the great question of organic evolution. I refer to the study of genetics, which deals with the question mainly of the transmission of the properties of the organism; but it deals with even a larger subject than that. It looks into and tries to determine the laws which govern the origin of the characters of individuals, whether plants or animals, whether those characters have been acquired by inheritance or in some other way. The subject is of the utmost interest and practical importance to man from three points of view. It has a bearing on philosophy of a most important and far-reaching kind through the theory of organic evolution. That theory largely depends for its proof upon the science of genetics. Secondly, it has a most important bearing upon practical questions affecting breeders of animals and raisers of plants, and also upon man himself in connection with practical legislation. This brings me to the third point, in which this subject specially appeals to us, and that is what I may call its bearing upon ethics. This is, of course, closely connected with the last.

We are constantly confronted with questions in which we have to think, not only of the advantage and happiness of those alive at the present moment, but also of those not yet born who will succeed us on the earth. The decision of these questions is one of the most important and burning subjects which can be put before us. They often crop up in legislation, and yet we are quite unable to answer them because of the very little knowledge we possess of the laws which govern the transmission of characters from generation to generation.

The interests of future generations often appear to be in conflict with the immediate pleasure and happiness of the living, and we are confronted with the question whether we ought to give way to our own humane and benevolent feelings or whether we ought to set our teeth and deal ruthlessly with a number of people who must appeal to our pity, lest by saving them from elimination we should bring about an increase in the number of people who are unable to hold their own, and so weaken the nation and increase for the next generation the difficulties which we set out to cure. I do not pronounce any judgment on these questions; I merely wish to emphasise the immense, the transcendent importance, from the human point of view, of the investigations which the study of the question of evolution has caused biologists to carry out into that most difficult of all subjects, heredity, and of obtaining clear ideas upon the subject. These, I admit, are elementary examples, and probably familiar to most of you—and they might be largely added to from other branches of zoology, such as entomology, marine fauna, and physiology—of the great practical achievements which have followed from the recognition of the fact, possibly appreciated in some ancient civilisations,[1] but in modern times first understood by Bacon and his compeers, that natural phenomena are in themselves, and without reference to immediate utility, proper subjects of man's inquiry, and that all progress must be based on their thorough and accurate investigation.

The genesis of a new idea is so difficult, and the amount of work necessary for its complete elucidation and development so vast and detailed, that many eminent men, taking only a short period of time and not realising the minute steps by which the advance of knowledge takes place, have been led to doubt the value of scientific investigation in the higher realms of pure knowledge, even to the extent of speaking of the bankruptcy of science. Others, again, perceiving the apparent aimlessness of many investigations and undervaluing the motive which urges them on, have come to look with a certain contempt upon the man of pure science and his slow and plodding progress. What is the good of all this work at unimportant details? What do you get out of it, and what pleasure do you find in it? they ask, and when they are told that the humble worker usually gets nothing out of his work except the pleasure of doing it, and that his motive is nothing more elevated than the satisfaction of his curiosity, there does appear to be, it must be admitted, some justification for the contemptuous indifference with which the poor researcher is regarded by a considerable section of the population, as is shown by the almost entire absence of support of pure scientific research on the part of the Government. With the exception of an annual grant of 4000*l.* a year given to the Royal Society, I think I am correct in stating that the Government affords hardly any support to science save to such as is concerned with teaching or with some practical problem; and when one remembers the composition of Governments and the manner in which, and the reasons for which, they are chosen, one cannot unreservedly blame them for this attitude. The best method of fostering research is a difficult problem, and I can well understand that a modern democratic Government, depending as it does upon popular support with its attendant popular mandates, should shrink from dealing with it. To do so would bring them no popularity and no votes, and too often they are not really aware of its immense importance to human progress, and when they are they have great difficulties to face.

For it is impossible to organise research on a commercial basis. "All attempts," says Prof. Nichols, of Cornell, "at a machine-made science are doomed to failure. No autocratic organisation is favourable to the development of the Scientific Spirit. No institution after the commercial models of to-day is likely to be generously fertile. You can contract for a bridge according to specifications. No one, however, can draw up specifications for a scientific discovery. No one can contract to deliver it on a specific day for a specified price, and no employee can be hired to produce it for wages received."

This it is impossible to get the public to understand even when it has undergone the process which we call education. You may establish paid posts for scientific research, but you cannot be sure that you will get research, for science is like the wind that bloweth where it listeth, and that is what our educated public do not like. They want something for their cash, and they will not wait.

Even those who are aware of the immense value of pure research forget the fact that the aptitude for scientific investigation is as rare as the gift of poetry, to which in many respects it is allied, for both are creative gifts, rare and precious. They forget that it is impossible to ascertain without trial whether a man possesses it or not, and that this trial can only be made when he has passed his student days and looks to support himself by his own exertions. To provide for this support money is needed, and studentships must be established in considerable numbers, from the holders of which those who show that they possess the gift of research can be selected and promoted to higher posts in which their gift can find full opportunity; but we want more than this—we want compensation for those whom we have encouraged to make the trial and who have failed to show that they possess the gift, and an outlet by which they can emerge and find work in practical life.

---

[1] There are, as is well known, indications that research into natural phenomena was practised and esteemed in some ancient civilisations which have been destroyed by the inroad of barbarians or by other causes. One of the most striking of these indications is the record in one of the sacred books of the Hindus which cannot be less than 1400 years old, and is probably much older, that malarial fevers are directly caused by the bite of mosquitoes. Attention was first diected to this record by Sir H. A. Blake, G.C.M.G., in 1905, while he was Governor of Ceylon (*vide* Journal of the Ceylon Branch of the British Medical Association, vol. ii., part i., 1905).

This has been and is a difficulty in all schools of science, for many are called but few are chosen. The situation is this: it is desirable that a large body of able young men should be encouraged to take up scientific research, but as experience has shown that only a small proportion of them will possess the qualities by which success in research can be attained, and as it is undesirable to encumber the progress and the literature of science by a host of workers who have no real capacity for research, it results that a time will arrive when a great proportion of those whom we have encouraged to give some of the best years of their life to this unremunerative work should be invited to find other occupations. What is to be done? We cannot throw them into the street. Some compensation must be given. There are two ways in which this can be done. One is the system of prize fellowships, which has for long been in vogue at the old universities, and which it has of late been the custom of those who have not really studied the matter to decry. Nevertheless, it is a good system, for it provides an income by which those who have given some of the best years of their life to this trial of their capacity can support themselves while they qualify for taking part in a practical profession.

A prize fellowship system, or something like it, is a necessary accompaniment of a university which induces a large number of young men to follow for a time the intellectual life; it acts both as an inducement and a compensation, and it would be a mistake and an injustice, in my opinion, to abolish it; but there is another way in which the difficulty can be met, and that is the way which has been adopted by the wise and far-seeing founders of the Imperial College, namely, by the combination of a school of science with a school of technology. If you have incorporated in your school of science a school of applied science, and if you at the same time take care that none but able men are allowed to enter the research grade, and if you establish, as you must do if you honestly work your school, a connection with the great industrial interest of the country, you have all that is necessary for the disposal of those men who, for whatever reason, find themselves unable to follow a life of pure science. As is well known, the faculty for pure, apparently useless, research in science is often possessed by men without any aptitude for practical application of science or desire of practical success and the wealth which practical success brings, while, on the contrary, many minds of the highest order cannot work at all without the stimulus of the thought of the practical outcome of their labour.

In our college there is room both for those with the highest gifts for pure scientific research and for those with the inventive faculty so important in the arts, or with the knowledge and ability for controlling and organising great industrial enterprises; and, what is more, the combination of the two types of mind in the same school cannot but be of the greatest advantage to both, not only on account of the atmosphere which will be created, so favourable to intellectual effort, but also because good must result from the contact in one school of minds whose ultimate aim is to probe the mysteries of nature and to acquire control over her forces.

As Prof. Nichols has well said in pointing out the dependence of technology on science:—"The History of Technology shows that the essential condition under which useful applications are likely to originate is Scientific productiveness. A country that has many investigators will have many inventors also. . . . Where science is, there will its by-product technology be also. Communities having the most thorough fundamental knowledge of pure science will show the greatest output of really practical inventions. Peoples who get their knowledge at second hand must be content to follow. Where sound scientific conceptions are the common property of a nation, the wasteful efforts of the half-informed will be least prevalent." These are sound conclusions, and experience has shown that if the terms are interchanged the same remarks may be made with equal truth of the good influence which results to a school of science from its association with a school of technology.

Before concluding, it may be well to say a word as to the origin of the great imperial institution in the interests of which we are met here to-day. It may justly be described as the natural and necessary outcome of the scheme for scientific instruction which was originated by that great Prince whose memorial stands near the end of Exhibition Road, and to whom science and art in England owe so much. He dreamed a dream which his untimely death alone prevented him from realising. Had he lived, who can set a bound to what he would have achieved for science and education in England? It is a most happy circumstance that the final stages of the realisation of that dream should have been entered upon in the reign, and have received the sympathy, patronage, and active support of his great son, our most gracious King, who is working in so many directions for the welfare and happiness of our race.

There is one further point I must touch upon. In the few remarks which I have had the honour to make to you, I have endeavoured, however imperfectly, to embody in words certain thoughts which bear upon a great subject. I thank you for the patience with which you have heard me. Whether I have produced the effect I desire I know not, but I know this, that even if I had the tongue of men and angels, no words of mine could have been so apt, so expressive as the magnificent deed of Mr. Otto Beit recorded in to-day's newspapers. It is impossible for me to pass this over in silence, so closely is it connected with the subject of my address. There are two ways of manifesting thought, by word and by action. Mr. Beit has chosen the latter and far more effective way. We can only express our respectful admiration and gratitude for his generosity, and our thankfulness that a man should exist among us with the power, the insight, and the true humanity to do such a splendid deed.

THE NEW DEPARTMENT OF BOTANY AT UNIVERSITY COLLEGE, LONDON.

ON Friday, December 17, the new botanical laboratories at University College, London, were formally opened by Dr. D. H. Scott, F.R.S., the Vice-Chancellor of the University of London (Prof. M. J. M. Hill, F.R.S.) presiding. Dr. Scott, in the course of a very interesting address, said that botany has been more fortunate in that college than in many others of more modern origin, for the subject has always been recognised from the foundation of the college as an independent science co-equal with her sisters. In the long period from 1828 to the present time there have only been three appointments to the chair, viz. Profs. Lindley and Daniel Oliver, and the present occupant, Prof. F. W. Oliver. After giving an outline of the history of the department and of his own connection with it, Dr. Scott spoke of the various branches comprised in the subject. Systematic botany is the oldest branch, but it never can become old-fashioned. It is not needed less now than a century ago. At one time there was a tendency to neglect it somewhat in favour of the study of the structure and functions of some few plants which have been favoured with selection as types. Now the pendulum has swung the other way, and its importance is fairly recognised in teaching. It would be disastrous if systematic botany fell into neglect, and it would be peculiarly discreditable to English people, because systematic botany is specially a glory of this country.

Referring to the Hookers, Bentham, C. B. Clarke, and Daniel Oliver, Dr. Scott said it would appear to be a characteristic that the ablest minds have been attracted towards systematic botany. Comparative anatomy, he said, is now pressed into the same service as systematic botany. Comparative anatomy is particularly a study of the modern English school. These two branches are now subservient to questions of evolution, the search for relationships having become identified with the attempt to race descent. It is from this point of view that the English school of anatomy has been directed, and this has led to a close union with fossil botany, the direct investigation of the historical documents of the rocks, so often best recorded in anatomical characters. In this way the modern study of fossil botany, based chiefly on structure rather than on the often deceptive external appearances of the fossils, has been active in an advantageous way in recent times, and has given it a more truly comparative and evolutionary character than it ever had before. After referring to physiology, ecology, and cytology, Dr. Scott expressed the view that genetics, the study of variation and heredity, is probably the leading subject of all at the present day. It is the subject by which this age will be remembered, though the study is only actively beginning now. The impetus given by Darwin, already felt in many other directions, is only beginning to be felt in this particular direction.

A vote of thanks was moved by Lord Reay (chairman of the college committee) and seconded by Prof. F. W. Oliver, who, on behalf of the members of the department of botany, presented to Mrs. D. H. Scott a piece of jewellery as a souvenir of the occasion.

The opening ceremony was attended by a numerous company of botanists, members of the University Senate, college committee, and professorial board. The exhibits shown in the rooms of the new department included portraits of former members of the staff, a selection of records connected with the ecological work of the department at the Erquy station, fossil plants from the groups of the Pteridospermeæ and Cycadophyta, and other work connected with the work of the department.

The following is a description of the new department, which takes the place of a series of inconvenient and indifferently lighted laboratories in the central building.

The suite of rooms now allotted for the accommodation of the department of botany has become available through the transfer of the department of physiology to new quarters in the south quadrangle. Built in 1878, under the supervision of the late Sir J. Burdon Sanderson, for purposes closely similar to those to which they are now being put, it has not been found necessary to make any structural alterations of moment.

In all, fifteen rooms are included in the department; they are situated on either side of a corridor which runs the whole length of the top floor of the north wing of the college. The rooms have been allocated as follows:—

On the north side, following the lecture-room, is the professor's laboratory, and adjoining this the elementary and advanced laboratories. These two rooms have been thoroughly overhauled, and staging has been erected so that the working tables get the full benefit of the excellent lighting. The benches are arranged in four tiers, and are fitted with water, gas, and electric lamps. Each of these laboratories has seating capacity for forty students. Beyond these rooms is a large room set apart for original investigations, especially in anatomical and microscopic work. The available space is increased by the existence of a gallery along the south side with separate windows. Communicating with the research room is the chemical physiology room, with benches equipped for twenty-four workers. As in the research room, there is a gallery lighted from the south, and suitable for special investigations.

On the south side of the corridor the rooms are all top-lighted in order to conform with the style of architecture in which the façade of the college has been built. The first room on this side has been fitted up as a departmental library, in which the collection of pamphlets, numbering about 4000, has just been classified, and is now about to be catalogued.

Next the library comes the large apse room, which will be used as a herbarium and ecology room. Here are being arranged the ecological collections and photographs, vegetation charts, &c., connected with the field work of the department at Erquy and elsewhere, together with biological specimens generally. The overhead lighting of this room makes it very suitable for the examination and exhibition of specimens, and for mapping and similar purposes. The concave apsidal end of this room has been fitted with a continuous, semi-circular desk for demonstrations and temporary exhibits—a purpose for which it is well suited.

Next to the ecology room, the old animal room has been converted into a central store for preserved material of all sorts. On one side of this store potting benches have been erected for the service of a small conservatory which lies beyond. This greenhouse will be used as an adjunct to physiological work and for raising plants for class purposes.

INDIAN GUILD OF SCIENCE AND TECHNOLOGY.

ON Saturday, December 18, a large number of Indian students assembled at the University of Leeds to inaugurate an Indian Guild of Science and Technology. This movement is the outcome of the noteworthy migration of Indian students during the past three or four years to countries where they seek to equip themselves with scientific and technical knowledge to aid in the development of Indian industries. The object of the Guild is to promote intercourse between these students and to assist them in every possible way to attain their common aim. The members hope, by associating themselves in this way, to assist other incoming students, and to cooperate, when they return, in promoting science and its applications to industry and sanitation. They hope also to stimulate an organised movement in India with these objects.

The meetings on December 18 were attended by students from a considerable number of centres of higher education, and the proceedings were marked by unanimity and enthusiasm. At a preliminary meeting the general constitution of the Guild was drawn up. In the afternoon the inaugural meeting was held, when Prof. A. Smithells, F.R.S., was elected president for the year, and delivered an address. Prof. Smithells outlined the work which he thought the Guild might accomplish, and enlarged upon the importance of science in relation to the development of the resources of India and the improvement of the condition of the people. He insisted upon the importance of not allowing an educational system to arise which should lead intelligent Indians mainly to the destiny of lawyers and clerks, and he maintained that India could not at this day develop its industries without a much greater application of science than there had been in the early days, or was even at the present time in Great Britain. Though there were many signs of scientific activity in India, and much excellent work was being done by the Government, he thought that a national effort among the younger men of the country might do much towards aiding the existing agencies.

Lord Airedale, as a representative of the iron and steel industries, who for more than half a century had been associated with a large manufacturing concern, made an interesting speech, in which he recalled examples of the benefits conferred by science upon industry. He urged his hearers not to let their poetic imaginations run away with them, but to apply themselves practically and industrially to the attainment of scientific knowledge, and then to concentrate on one or two definite objects.

Among speeches made by the students was an eloquent plea, by Mr. R. N. Sen, for regaining the lost glory of India by the assimilation of all that is best in western scientific and technological knowledge.

In the evening the members of the Guild assembled at an inaugural dinner. Many encouraging messages had been received from men of science, including the presidents of the Royal Society, the British Association, the Institute of Chemistry, Sir Henry Roscoe, Prof. Witt, of Charlottenburg, Prof. P. C. Rây, of Calcutta, Sir Alex. Pedler, Prof. Meldola, Prof. Dunstan, and others. Lord Airedale, Sir Henry Roscoe, Sir W. Ramsay, K.C.B., and Prof. O. N. Witt were elected patrons, and the following were elected sectional hon. presidents:—Prof. Schäfer, F.R.S. (Edinburgh), Prof. Barr (Glasgow), Prof. Procter (Leeds), Prof. Cadman (Birmingham), Prof. Knecht (Manchester).

The subscription to the Guild is 10*s.* entrance fee and 10*s.* annual subscription. The secretary is Mr. M. A. R. Paniker, The University, Leeds.

THE PHYSICAL SOCIETY'S EXHIBITION.
